In contrast to this case, on July 21st, 1920, I examined a temporary porter, aged 34, who on the previous April 17th had fallen backwards about 5 feet and hit the back of his head. He did not lose consciousness, and there was no wound of his scalp. He immediately left his work. He did not go to a hospital, but was attended by his panel doctor. He went to bed for three days, but since then had been walking about. To me he complained of weakness and giddiness and pains in his head. There was a marked tremor of his hands while he was under observation, but this ceased when his attention was thoroughly engaged in conversation. I could find no evidence of any organic nervous disease, nor was there a scar on, or tenderness of, his scalp.

He neither drank nor smoked; he was unmarried, and lived with his parents. I could find nothing the matter with him, and suggested that he should return to work. He did not do so, and on September 30th he went before the official medical referee, who certified that he was suffering from "mild traumatic neurasthenia," and that his condition was such that he was fit for light work and should resume his ordinary work in a month. How anyone can predict that traumatic neurasthenia, even of the mild variety, is going to cease in a month is a question which might be indefinitely and uncertainly discussed.

The porter accordingly resumed his ordinary work on November 19th, and with the ill luck that attends these "neurasthenics," on November 20th was struck on the side of the head by the handle of a hand truck. He said that he lost consciousness. He was taken to the Poplar Hospital, but was not detained, and went home in an omnibus.

I saw him on February 11th, 1921. He had remained at home ever since, and was quite unable to work or even to perform, on occasion, such domestic labour as to carry coal upstairs for his mother, a woman aged 78. He was, however, able to take walking exercise up to two or three miles. He complained to me of inability to sleep, that he became giddy, and that he had pricking sensations in his eyes and pain in his head. He also complained of great weakness. The objective evidence of his condition was tremor of his hands, as on the previous occasion, and a pulse rate of over 100.

The curious mentality of this man may be realized by this incident. When endeavouring to ascertain what he did with himself during these long periods of leisure, I asked him if he read any books, and what books he had read. He told me that there was a copy of *Robinson Crusoe* in his house, and I strongly advised him to read it. He replied to me, somewhat reproachfully, that he did not read secular books, but only the Bible. He described himself as an "undenominational non-sectarian."

As the man had been in the company's employ for only a year, and during practically all that period had been drawing compensation for two comparatively trivial accidents, and as he appeared to be rather unlucky in the matter of accidents, and the official referee had stamped him with the hall-mark of traumatic neurasthenia, I advised the company to get rid of him at any cost. This was achieved at the price of £175.

TRAUMATIC NEURASTHENIA.

The mention of traumatic neurasthenia brings me to a very thorny problem. What is traumatic neurasthenia? It is our inability to answer this question, or rather the inability of all of us to give the same answer, that makes us, I think rather deservedly, the butt of the legal profession. As Lord Melbourne said, it doesn't matter what we say, so long as we all say the same thing.

[illegible] misnomer. The word neurasthenia is "nerve [illegible] shock," or essentially "nerve exhaustion"—a very [illegible] as public, as it either suggests that they [illegible] mixed bag of effort far beyond their legitimate [illegible] ever trivial in consequence (nervous breakdown," and often "that some virtue from that [illegible] to call, nervous system, has been lost to [illegible] their own (traumatic neurasthenia, a condition heroes or martyrs, both [illegible] that [illegible] of our profession who hold [illegible] with charity and wherever inflicted, [illegible] only in its physical condition of the [illegible] tic signs and symptoms, [illegible] 14, who have, to which the term [illegible] in January, 1929.ed.[3] I am not one [illegible] a thing without presumption, I do not believe that there is such an entity as traumatic neurasthenia or psychasthenia. I believe that the cases which pass under these names are those of people with some derangement or disorder of what I prefer to call temperament, which renders them fearful, introspective, gloomy, and anxious, with all the physical consequences which such qualities connote. I do not suggest that such sufferers should not command our sympathy and, on occasion, should not obtain compensation when their condition, as it very often is, has been the fault of another; but each case should be decided on its own symptoms, and not under the name of a large and indefinite generalization. For instance, a nervous man may, as the result of an accident, be rendered more nervous and apprehensive, or a man hitherto care-free may have assumed a habit of anxiety and introspection. Both of these are deserving of our sympathy, and should receive compensation.

It may be argued that all this is merely a question of words, but I believe that it is very much better for the patient that he should know that though, as the result of the accident, he has become more fearful than he was, or more prone to worry about himself and his future prospects, he is not suffering from a mysterious physical condition which is affecting his mind and darkening his outlook on life. It would, I am certain, be more easy to assess these cases and to explain the degree of disability to the legal audience with whom the ultimate award rests.

I admit that, as the result of an injury, a man's temperament may undergo an alteration; he may become more irritable, more fussy, more fearful, and the rest; but to give that undoubted fact a name like traumatic neurasthenia is to give the layman, and often ourselves, quite a wrong conception of what has happened.

Once a condition has a name it requires no further definition. Even if the name means nothing it becomes part of the established order of things,[3] and if the condition for which the name stands is not well defined anyone can attach to it such meaning as he likes. To my mind the mental or temperamental conditions which follow injuries are not yet sufficiently defined to deserve a name, and it would be more convenient for the patient, for the doctor, and for some future judicial authority if the exact condition of which the patient complains were explained in plain English terms, and no attempt were made to give it any name.

"Traumatic neurasthenia" seldom, if ever, follows very serious injuries or disabling injuries, like fractures of the limbs. It is almost invariably restricted to injuries which result from accidents which are due to the alleged fault or negligence of others.[3]

I could say much more on this subject, but it has been said much better in a paper by Sir Farquhar Buzzard and published in the *Lancet* for 1923, vol. ii, which I strongly commend to your notice.

"RAILWAY SPINE."

In the sixties of the last century, owing to the increasing rate of railway travelling, a number of cases of "concussion of the spine" were reported, several of which had paraplegia. They formed a large part of that curious entity "railway spine."

In the early eighties my late colleague and teacher Mr. H. W. Page showed that these cases were not uniform, and could be accounted for by lesions other than concussion. Some were actual organic lesions of the spinal column or cord, cases in which the cord had been crushed but the bones had sprung back into their place, cases of haemorrhage into and around the cord, and, in many cases, inflammatory lesions, some of which were obviously syphilitic. There were also a large number in which the symptoms were purely functional and in which there had been no damage to the cord or spinal column. Gradually the conception of concussion of the spinal cord, analogous to cerebral concussion, has died a natural death, and with this, I think, has disappeared a large proportion of the cases of functional paraplegia which in the sixties and seventies used to follow railway accidents.

I have unfortunately no figures, but I have a strong impression that whatever direction functional disabilities

following railway accidents may take now they do not assume the character of paraplegia with anything like the same frequency which they did in those days. I venture to think that this, in a rough way, is a case of supply and demand. The medical profession had conceived the idea of concussion of the spinal cord with a resulting paraplegia, and the public immediately supplied the cases. When the demand failed the supply gradually petered out. Analogies are dangerous, but is it not possible that our trite label of "traumatic neurasthenia" helps to keep up the supply?

On August 1st, 1923, I saw Mr. Z, a man aged 58, who was an overseer in the post office, and had been in its service for forty-four years. On February 29th, 1928, he was in the post office van in the front part of a train which entered a London terminus at an excessive speed and came into sharp contact with the buffer stops at the end of the platform. As a result of the accident Mr. Z became unconscious for a short time. He was admitted into a hospital and remained there for three days. There was no fracture of his jaw or skull, and he was reported as having suffered from slight concussion. He remained in bed for six weeks, and then got up and moved about his house. He had been away for a change, but had had to return home on account of his condition.

He was a very unhappy-looking man. He was entirely wrapped up in himself and his symptoms, and it was difficult to rouse him from this condition of egotistic misery. Neither his doctor nor another surgeon nor I could find any evidence of organic disease of his nervous system. His condition was, I believed, mental, and partly due to the fright which he had experienced at the time of the accident, and partly to his anxiety that he would not recover, and that he suffered from some obscure hurt to his nervous system which was likely to become worse. I also thought that his condition was accentuated by the anxiety of his family that he would not receive compensation adequate to the discomfort to which he, and incidentally they, had been put.

Mr. Z's symptoms were headaches, loss of appetite (he had not lost weight), and attacks of giddiness (though he never fell). He had lost four teeth from his lower jaw as the result of the accident. He was certainly not fit to be an overseer in the post office, and he would have been much too frightened to have resumed his position in the post office van of a train; besides, I did not think that a man of his age would be able to take up his original duties after having fallen out of his routine for a period of over six months. I saw no reason why he should not recover, and I saw nothing in his condition which was likely to shorten his life. I thought that he would be more cheerful if he could escape from his present environment.

I reported on these lines to the railway company and Mr. Z received a sum in compensation which I hoped would allay both the anxieties of himself and his family; it was not perhaps quite as much as was asked—that, if given, would have probably been responsible for a nervous breakdown on the part of the solicitor, as he would have feared that he had not done his client justice.

INJURIES OF THE BACK.

It is part of our language that the back is an important item of our anatomy. We talk of a man having or not having "backbone." One is exhorted to put "one's back into it." It is on our "backs" figuratively and in reality that we bear our burdens. Amongst manual workers the "back" is peculiarly sacrosanct. It is also peculiarly vulnerable. It easily weakens, it is unduly susceptible to cold, and to it are attracted strains and sprains as iron filings to a magnet. It is also singularly tenacious of anything which it has acquired, and an injury to the back, even if apparently slight, is always a long business.

I am not going to refer to the gross injuries of the spinal column and cord, such as fracture dislocations; they are simplicity itself compared to what are miscalled the "minor injuries" of the back, and it is with these that we are principally concerned in matters of "compensation." Much might be written, and much has been written, particularly in America, about "backache" and "low back pain" following injuries of often quite a trivial nature, and I know of no class of case which presents such extraordinary difficulties as do these.

X rays have shed considerable light on some of the pathological conditions underlying the complaint of a painful back, but they have also done much to confuse the issue in individual cases. What, perhaps, is not always realized is that it requires considerable skill and much experience to take a reliable *x*-ray photograph of the spinal column. Photographs to be of value should be taken in more than one plane, and should, where it is possible, be stereoscopic. If it requires technical skill and experience to take an *x*-ray photograph of the spinal column, it also requires knowledge and experience to interpret the photographs, and this particularly applies to photographs of the lumbar and sacral spine.

An *x*-ray picture of the fifth lumbar vertebra presents its own peculiar difficulties, owing partly to the wedge-shaped body of the vertebra and to its close relation with the massive part of the sacrum. Its so-called sacralization, either by union with the body of the first sacral vertebra or by the articulation of the transverse process with the ilium, has been regarded by some as the cause of symptoms, and as the result of injury. The want of union of the two bodies of the neural arch has been mistaken for a fracture. This also has happened in the case of the transverse process of the first lumbar vertebra when the epiphysis of the costal element has failed to unite with the epiphysis of the transverse element. Split vertebral bodies which have been developed from two epiphyses and half vertebrae have presented appearances which have been mistaken for the results of injuries.

I could multiply examples like these, but I have said enough to show that considerable knowledge and experience are required before attempting to interpret an *x*-ray photograph of the spinal column. On the other hand, *x* rays have enabled us to diagnose compression fractures of the bodies of vertebrae and fractures of the lumbar transverse processes, both lesions almost impossible of accurate diagnosis without radiography. The *x* rays have also shown us how common and widespread are osteo-arthritic changes in the vertebral columns of manual workers, partly due to the daily stresses and strains of manual labour, but assisted by toxaemia from neglected pyorrhoea and septic teeth.

Let me give you, in conclusion, an example of a mistaken diagnosis.

A man, aged 26, on May 26th, 1927, while wheeling a barrow, stepped on a piece of loose rubble and fell forward. He saved himself by sudden and violent muscular effort, and while recovering his balance he felt a sharp pain in the lower part of his back. He reported the accident to the foreman, and rested until the dinner hour. When he tried to get up he felt a sharp pain in his back, and the latter became stiff. When he stood up he was unable to straighten his right leg without giving rise to pain in his back, suggesting the possibility that he had ruptured some fibres of origin of the psoas. He went home by train, and also went to his doctor and got some *liniment*.

The next day he went to the local hospital and was *x*-rayed, and, as a result, was admitted to the hospital on the following day. The radiologist's report was to the effect that the patient "had sustained a fracture of the body of his fifth lumbar vertebra and a partial dislocation of the body of the fourth vertebra on the fifth." He was kept on his back in the hospital, but owing to some misunderstanding between himself and the hospital authorities he took his discharge after ten days and went home in an ambulance, and continued in his own home to rest on his back with sandbags to steady him. After two months he went to a convalescent home, but felt worse when he returned. He was still under treatment when I saw him in January, 1928.

At this time he complained of "scalding pain" in his lumbar region. He said that he could not walk as well as he did. He also had pains at the back of his head, and occasionally had difficulty in making his water. I could find nothing wrong with him or with his back. He took his boots off and laced them up again while standing: an accomplishment many would envy. I had him *x*-rayed by Dr. Harrison Orton, who also examined the prints of the former *x*-ray photographs. Dr. Orton's stereoscopic photographs showed a perfectly normal fifth lumbar vertebra, which was neither crushed nor dislocated. The fourth vertebra was also *normal*. The appearances seen in the former photograph could be explained by the particular angle at which the photograph had been taken.

The patient had, for nearly a year, been living under the cloud of a broken back, and this alone, I think, might explain the nervous symptoms of which he complained. His own doctor and the surgeon at the hospital undertook to explain matters to him, and I understand that he was then persuaded to go back to light work.

A CASE OF RUPTURED EMPYEMA OF THE GALL-BLADDER ASSOCIATED WITH ASCARIS LUMBRICOIDES.

BY

R. WOOD POWER, M.B., F.R.C.S.I.,
HONORARY SURGEON, HEREFORD GENERAL HOSPITAL;
AND
H. W. JOHNSTON, M.B., B.Ch.,
LEOMINSTER.

GALL-BLADDER disease in young children has always been regarded as extremely rare, hence the occurrence of a case at the early age of a little more than 2 years makes it worthy of record.

W. W., an only child aged 2½, had been in perfect health until the present illness, except that for the previous fortnight, while staying with his grandmother, he had passed two round-worms. She had remarked that he was always twitching and that she could not satisfy him with food. She also said that he was "*full up with worms.*"

On January 26th of the present year he first showed signs of illness; on that day he went off his food and vomited everything he was given. The next day he was still unwell, but the vomiting ceased and he did not complain of any pain. On January 28th and 29th the condition was much the same; he was fretful, would not take food, but was very thirsty, drinking a lot of milk and tea. On the following day he was about the same, but no further vomiting occurred. He was seen by one of us for the first time, and some medicine was ordered. On the morning of January 31st he seemed a little better and took some bread and jam, but in the afternoon he complained of abdominal pain, and was flushed and appeared very feverish. The next day he was worse; he perspired very freely, and refused to eat or drink. There was no vomiting, but he still complained of abdominal pain. He was again examined, and it was thought that it might be a case of appendicitis. An enema was ordered, and a round-worm was passed in a good result. On February 2nd he was still disinclined to eat, and took only liquids; he was very irritable and perspired freely all day, and had five motions. About midnight he appeared very much worse, and complained of severe abdominal pain. The next morning he was ordered to hospital.

On admission the child looked ill. His temperature was 99° F., the pulse 140. He was very restless; the tongue was dry and coated, and the abdomen was rigid all over. A diagnosis of acute appendicitis with generalized peritonitis was made. Within a few hours of admission a paramedian incision below the umbilicus was made and on opening the peritoneum free pus was encountered. Examination of the appendix revealed that it was not the offending organ, and a search for a Meckel's diverticulum was also fruitless. On palpating the upper abdomen a mass was felt, and the incision was enlarged up to the costal margin. The omentum was found wrapped around the gall-bladder, from which, on freeing the omentum, thick pus was seen to be oozing. A clamp was applied to check the pus, but the slightest traction resulted in the forceps tearing away. All attempts to prevent the pus escaping were abandoned, and it was mopped up until the gall-bladder was emptied. The common bile duct was inflamed, but nothing abnormal was revealed by palpation; it was not opened. The gall-bladder was then removed and two drainage tubes inserted, one in the region of the gall-bladder and the other into the pelvis; the abdomen was then sutured.

After-History.—The usual post-operative treatment was carried out, and an enema given on the second day brought away a fourth round-worm; each of these worms measured about six inches. Widal's reaction was negative, and antihelminthic treatment was carried out, but no more worms were passed. The recovery was uneventful, and the child left hospital six weeks later quite well. The pus showed a mixed infection of *B. coli*, streptococci, and staphylococci.

This case presents two interesting and rare conditions: first, the occurrence of an acute empyema of the gall-bladder in such a young child, and secondly, its association with the *Ascaris lumbricoides*. It may be of interest to review the literature of these two conditions separately.

Acute Perforated Empyema of the Gall-bladder in the Young.

From a perusal of the literature this condition appears to be of very rare occurrence. Griffith states: "Acute cholangitis and cholecystitis are very infrequent conditions, but may occur after typhoid fever or from sepsis. Cholecystitis of a more chronic nature is probably not an infrequent sequel of typhoid fever. Tuberculosis of the gall-bladder is sometimes seen."

Reid and Montgomery of the Johns Hopkins Hospital collected eighteen cases of typhoid fever in children under the age of 15, who either died from, or were operated on for, complications arising in the gall-bladder. They preface their tabulation with the statement that "in children, acute suppurative cholecystitis of any kind is rare. Altogether there are only about twenty reported cases."

We have tabulated all the reported cases of ruptured empyema of the gall-bladder occurring in patients up to the age of 15 which we can find in the literature of this subject. It will be seen (Table I) that with the exception of the second case, in which the age is not stated, the present case appears to be the youngest yet reported.

Cholelithiasis, it will be observed, occurred in three of these cases. We have been able to trace 139 cases of this condition in which the patients were under the age of 16, and only in the above-mentioned cases was it associated with empyema of the gall-bladder. As two of these patients had also typhoid fever it may be presumed that

TABLE I.—*Reported Cases of Ruptured Empyema of the Gall-bladder.*

Year.	Author.	Age.	Sex.	Cholelithiasis.	Pathology.	Symptoms.	How Diagnosed.
1835	Husson	8	Unknown	No	Peritonitis; perforation of gall-bladder	Typhoid fever	Autopsy.
1852	Archambault	Infant	Unknown	Yes	Ulcerative cholecystitis, perforation of gall-bladder	Typhoid fever; peritonitis	Autopsy.
1853	Barthez and Rilliet	12	Unknown	No	Ruptured gall-bladder; large abscess	Typhoid fever	Autopsy.
1864	Chédevergne	15	Unknown	No	Ulcerative cholecystitis	Typhoid fever	Autopsy.
1882	Steadman	13	F.	No	Ulcerative cholecystitis; perforation of gall-bladder	Typhoid fever; peritonitis	Autopsy.
1882	Steadman	6	F.	No	Perforated gall-bladder	Typhoid fever; peritonitis	Autopsy.
1884	Bond	10	M.	Yes	Perforated empyema of gall-bladder	Typhoid fever	Autopsy.
1892	Treves	10	Unknown	Yes	Abscess in back from which calculus was discharged	Indigestion; vomiting	Symptoms.
1893	Chiari	12	Unknown	No	Ruptured empyema of gall-bladder	Typhoid fever	Autopsy.
1895	Alexieef	5	Unknown	No	Ruptured gall-bladder; culture *B. typhosus*	Typhoid fever; peritonitis	Operation.
1906	Dover	13	M.	No	Ruptured gall-bladder	Peritonitis	Operation.
1908	Ashurst	12	M.	No	Perforation of gall-bladder	Typhoid fever; peritonitis	Autopsy.
1922	Howze	5	Unknown	No	Acute gangrenous cholecystitis	Fever; biliary colic	Operation.
1924	Lowenberg	Child	Unknown	No	Perforation of gall-bladder; peritonitis	Typhoid fever	Operation.
1924	Bittner	9	Unknown	No	Suppurative cholecystitis; perforation	Typhoid fever	Operation.
1924	Bittner	9	Unknown	No	Suppurative cholecystitis; perforation	Typhoid fever	Operation.
1924	Bittner	11	Unknown	No	Suppurative cholecystitis; perforation	Typhoid fever	Operation.
1924	Fischer	10	F.	No	Empyema of gall-bladder	Typhoid fever	Autopsy.

TABLE II.—*Reported Cases of Ascaris lumbricoides of the Gall-bladder.*

Year.	Author.	Age.	Sex.	History of Ascariasis.	Symptoms.	Operative Findings.	Result.
1850	Heaviside and Bloch	—	—	Two cases reported, no details.			
1765	Lorry	—	—	Vomited an ascaris	Convulsions		Necropsy: 3 ascarides in gall-bladder.
1918	Aviles	33	F.	Vomited ascaris	Gall-bladder colic	One ascaris in gall-bladder	Cholecystostomy.
1920	Tyau	—	M.	Ova found in stools	Pain and mass in gall-bladder area	- -	Necropsy: 9 ascarides in cystic duct.
1920	Eberle	9	M.	Treated for ascariasis	Pain and jaundice	Ascaris in gall-bladder.	Cholecystotomy.
1922	Butt	30	F.	Frequently passed ascarides in stools	Biliary colic	One ascaris in gall-bladder	Gall-bladder closed without drainage.
1928	Morton	45	F.	Vomited ascaris day before operation	Gall-bladder pain five weeks	One ascaris in gall-bladder	Cholecystectomy.

cholelithiasis plays but little part in the etiology of empyema of the gall-bladder in the young.

The chief factor in the etiology of this condition is typhoid fever. It will be noted that it is the causative factor in fifteen of the recorded cases; the etiology of the remaining cases is not given. In the past typhoid fever has been very closely associated with biliary disease at all ages, but with its great decrease in recent years this condition should become still more rare. The etiology of empyema of the gall-bladder appears to depend on two conditions: (1) infection of the gall-bladder; (2) obstruction of the cystic duct, either by inflammatory oedema or by a foreign body. A. L. Wilkie has carried out some very interesting experiments on animals in regard to the etiology of gall-bladder infection. He has isolated a streptococcus from the cystic gland in the human being in 84 per cent. of cases of cholecystitis, and with the same organism has produced a similar condition in animals. He injected the streptococcus intramurally into the gall-bladder, the cystic duct being patent in one instance and ligatured in the other. In the case in which the cystic duct was occluded a chronic empyema occurred; when the cystic duct was patent a cholecystitis alone was produced. Similar results were obtained with intravenous injection of this organism. Wilkie has also shown that the bile inhibits the growth of these organisms; so it would appear that it is only when the gall-bladder has been occluded for some time and the bile loses this property that acute empyema occurs.

Non-suppurative cholecystitis in children under the age of 16 has been traced in 115 cases; the etiology in most of them has not been given. Forty-four are associated with calculi, but Potter is of the opinion that influenza, appendicitis, scarlet fever, diphtheria, etc.—in this order—can be preceding factors. Farr, who reported five cases, believes that appendicitis "is a frequent concomitant, if not an etiological factor." In four of these five cases the appendix was found to be in a pathological condition. One of his patients had had a recent attack of scarlet fever. Snyder, who reported three cases, states that in two of them there was a history of previous scarlet fever.

Association of Ascaris lumbricoides with the Gall-bladder.

The invasion of the biliary ducts by the ascaris appears from the literature to be of fairly common occurrence, but this parasite very rarely intrudes into the sanctum of the gall-bladder. There are only eight recorded cases (see Table II).

Aviles has pointed out that the pathogenicity depends on three characteristics. The first is a poison found in the extract of the worm; the second is the carrying of infection by its motile and migratory traits; the third is mechanical—the obstruction sometimes caused in a hollow viscus by a parasite or a group of parasites. The last two characteristics are of importance in considering the pathology of the present case.

It appears to be doubtful whether the ova can be hatched out in the human body. Huber says: "It may be positively affirmed that ova which contain embryos and which are still surrounded with the mulberry envelope, will develop into round-worms in the human intestine." Stiles, on the other hand, states: "The eggs of the ascaris will not hatch as long as they are in the human body. They must pass out and there undergo their changes. The young worm is developed inside the egg, the egg is then swallowed, hatched out in the stomach, crawls through the wall of the stomach, gets into the circulation, goes to the heart and lungs, up the trachea, down through the stomach to the small intestine, there develops further." It is difficult, then, to say whether the worm develops from ova already in the biliary tract or migrates there from the intestine. Tyau has found the ova in the gall-bladder, and, if Huber's theory is true, one would expect to find the ascaris as frequently in the gall-bladder as in the bile ducts. On the other hand, if Stiles is correct and they migrate from the intestine, it is little wonder that they so rarely invade the gall-bladder when one considers the size of the cystic duct. Referring to this point Deaver says: "In a normal condition of the duct it is impossible to carry the smallest probe through it owing to its double course and the peculiar condition of its mucous lining." Tonnelé has found an ascaris partly in the common duct and partly in the duodenum. It is probable that Stiles's view is correct.

The literature is replete with reports of the presence of this parasite in the bile ducts. Huber has collected sixty-eight cases; in one as many as eighty worms had passed up from the intestine. Rokitansky reported a case of a cretin whose hepatic and common ducts were sausage-shaped, more than an inch in diameter, and filled with worms; they had found their way into the smaller ducts; two were found in the duct of Wirsung. That they may cause biliary stasis has been shown by Bonnapart of Pisa, who reported a case of icterus which ended fatally, the cause of death being the presence of an ascaris in the common duct. Both ova and worms are reported as forming the nuclei of biliary calculi. Degorce reports a case of violent hepatic colic recurring for seven years; at operation many biliary calculi were removed from the common duct. The patient died six months later from pulmonary tuberculosis. At the necropsy about forty stones were found in the biliary passages, all of which contained eggs of the round-worm. On section one of the largest stones contained a filament 1½ inches long which proved to be a small ascaris. Pasley reports a similar case of a native boy, aged 12, on whom he operated for obstructive jaundice caused by biliary calculi. He states: "A curious cylindrical body was at once noticed in the centre of this stone, which on subsequent examination proved to be a portion of an ascaris worm."

Table II calls for little comment except the constant feature of the association of intestinal infestation with the parasite and symptoms referable to the gall-bladder. Morton in his summary calls attention to this point; he states: "These two constant features of the cases do not assure the diagnosis, but when elicited they should at least lead one to bear in mind the possibility of ascariasis of the gall-bladder."

Conclusion.

1. A case of ruptured empyema of the gall-bladder is reported at an early age.

2. The child had no previous illness usually associated with gall-bladder infections with the exception of ascariasis.

3. The number of worms generally found is two; the passing of four in this case would suggest the possible presence and migration of others.

4. Aviles (see above) has pointed out that the worms may carry infection and also cause obstruction in a hollow viscus. It is suggested that in the present case one or more migrated to the biliary tract, causing obstruction of the

cystic duct and subsequent infection in the gall-bladder. Although neither ova nor worms were found, it is probable that if they were present they would have undergone disintegration in the pus.

5. In view of the numerous cases reported in which small worms have been found in the common duct, we would advise that the common duct be opened and examined in all cases of gall-bladder disease associated with *Ascaris lumbricoides*.

CONTROLLABLE SPINAL ANAESTHESIA:

SOME RECENT EXPERIENCES WITH SPINOCAIN SPINAL ANAESTHESIA.

BY

R. A. GRANT, M.B., CH.B.GLAS., F.R.C.S.ED.,

SENIOR HOUSE-SURGEON, NORFOLK AND NORWICH HOSPITAL.

STIMULATED by the experience of several American surgeons who have been using spinocain spinal anaesthesia with success, and by the statement by Dr. Frank A. Kelly[1] that "all textbooks on spinal anaesthesia will have to be rewritten, as a result of the epochal work of Dr. George Pitkin," we decided to try spinocain in a varied number of cases at the Norfolk and Norwich Hospital, and to investigate the advantages claimed for this anaesthetic by Drs. Pitkin and Kelly at the recent meeting of the British Medical Association at Manchester.

All the cases were under the charge of Sir Hamilton Ballance, senior surgeon to the hospital. We have used spinocain in thirty-four cases in all. With the exception of the first one or two we have been agreeably impressed by the anaesthesia obtained and particularly by the comparative absence of toxic symptoms, noticeably of any serious degree of shock and other post-operative complications. Almost all the cases have suffered from some pulmonary, cardiac, or other complication contraindicating a general anaesthetic, and a few have been in such a serious condition that the operation would have been associated with serious risk if performed under general anaesthesia. Our experience has been confined to adults—eighteen females and sixteen males. We have not yet had any children in which spinal anaesthesia was indicated.

List of Cases.

1. Male, aged 65. Intestinal obstruction due to peritoneal bands.
2. Female, aged 19. Skin graft of leg.
3. Male, aged 68. Strangulated inguinal hernia (radical cure).
4. Female, aged 37. Intestinal obstruction (caecostomy).
5. Female, aged 35. Amputation of cervix.
6. Male, aged 44. Cystoscopy.
7. Male, aged 33. Skin graft.
8. Female, aged 72. Appendix abscess.
9. Male, aged 65. Right-sided colectomy for neoplasm of caecum.
10. Male, aged 62. Extensive anal fistula.
11. Female, aged 24. Carcinoma of stomach (jejunostomy).
12. Male, aged 78. Suprapubic prostatectomy.
13. Male, aged 23. Manipulation of Pott's fracture, and plaster.
14. Female, aged 36. Myomectomy.
15. Female, aged 49. Cholecystectomy.
16. Male, aged 59. Sliding bone graft of tibia.
17. Female, aged 60. Strangulated femoral hernia (resection of small intestine).
18. Male, aged 35. Psoas abscess.
19. Male, aged 73. Suprapubic prostatectomy.
20. Female, aged 50. Colpoperineorrhaphy.
21. Male, aged 63. Radical cure of inguinal hernia.
22. Female, aged 18. Lengthening of tendo Achillis.
23. Female, aged 55. Cholecystectomy and appendicectomy.
24. Female, aged 54. Subphrenic abscess and suppurative cholecystitis.
25. Female, aged 23. Hammer-toes.
26. Female, aged 41. Cholecystectomy and choledochotomy.
27. Female, aged 50. Subtotal hysterectomy.
28. Male, aged 62. Reduction of fracture tenotomy of tendo Achillis.
29. Male, aged 55. Fistula in ano.
30. Female, aged 54. Tumour of colon (colostomy).
31. Male, aged 55. Double inguinal hernia.
32. Male, aged 70. Suprapubic prostatectomy.
33. Female, aged 52. Carcinoma of colon (right-sided colectomy).
34. Female, aged 47. Strangulated femoral hernia.

It will be seen from the above list that the cases, if not numerous, are at least varied, and in every case but one we were able to finish the operation without the aid of a general anaesthetic and without undue anxiety about the patient's condition.

The longest period of anaesthesia was in a male aged 65 (Case 9). The patient had severe myocarditis, but though the operation lasted two and a half hours he stood it well. He died nine days later from a heart attack. Another case which shows well the length of anaesthesia which can be expected is No. 17. The patient had a strangulated femoral hernia of four days' duration, and the operation, involving resection of gut and radical cure of hernia, lasted two hours and five minutes. This patient was in a very serious condition on admission, yet she gave no anxiety during the operation. These two cases and others in which the operation lasted over two hours serve to show that, provided sufficient spinocain is given, there need be no fear of the anaesthesia passing off.

In the above list there have been three deaths, none of which could be attributed to the anaesthetic. There has been no case of severe post-operative toxic symptoms. A few patients have vomited a little during the first twelve hours, and several have complained of slight headache and stiffness in the posterior muscles of the neck; apart from these, the convalescence has been smooth, and almost all who have experienced a general anaesthetic previously declare their preference for the spinal anaesthetic.

In our first few cases, while we had 100 per cent. successes in operations upon the perineum and lower extremities, there was considerable difficulty in gaining anaesthesia above the umbilicus sufficient for an abdominal operation of any length. This difficulty has, however, been easily overcome, as will be shown later.

Spinocain appears to have a selective action, the patient feeling some vague sensations of touch, but yet not complaining of any pain. Sensory fibres conveying temperature and touch are undoubtedly less affected than those conveying pain, the latter being completely paralysed along with all motor nerves below the spinal block.

Technique of Spinal Injection.

With a few important modifications we have followed the technique devised by Dr. Pitkin, and used needles of 20 and 22 gauge, which undoubtedly traumatize the spinal theca less than the ordinary lumbar puncture ones. These needles have an accurate bayonet-fitting joint with the Pitkin syringe, which is made in three sizes to contain 2, 3, and 4 c.cm. of solution. We have confined ourselves to the solution of light spinocain of specific gravity of 1005, containing 200 mg. of novocain and 2.2 mg. of strychnine sulphate, dissolved in 2 c.cm. of a special solvent consisting of alcohol 14.5 per cent. and sterile water, with the addition of amylo-prolamine, which is supposed to prevent diffusion of the anaesthetic fluid. In conjunction with the above we have used the ephedrine-novocain ampoule of 1 c.cm. containing 10 mg. of novocain and 50 mg. of ephedrine, these being the two solutions used by Dr. Pitkin and manufactured by the Metz Laboratories of New York. Following upon an article by Dr. Falkner Hill[2] we have also used planocain, manufactured by May and Baker, which is really strychnine-free spinocain, and theoretically would appear to be better, the strychnine tending, as Dr. Hill has stated in his article, "to break down the internal resistance of the spinal cord, so that a definite stimulus tends to produce a bigger motor response than in normal conditions."

Following the usual preparations for an abdominal operation, the patient is brought to the anaesthetic room half an hour before the time for the operation, and an injection of omnopon 1/2 grain and hyoscine hydrobromide 1 100 grain given, which serves to allay fear or apprehension. The injection is given in the usual position, the patient lying on his side, the knees being drawn well up and the neck flexed forward. The contents of the ephedrine-novocain ampoule are used to anaesthetize the path down to the spinal theca. A fine-bladed scalpel is then passed along the anaesthetized route, and this, we have found, breaks down the resistance of the ligamentous structures, enabling the spinal puncture needle to pass down to the theca without using the slightest force, and the dura can be punctured with ease. We usually inject between the second and third lumbar vertebrae, though, provided one keeps to the lumbar region of the spine, the actual site does not seem to matter. The patient should feel no pain at all.

Mixing the solution with the cerebro-spinal fluid, to the extent recommended by Pitkin, we have found tends to diminish the depth and length of the subsequent anaesthesia and also to delay the start; hence, once the cerebro-spinal fluid appears, we draw up 1/2 c.cm., slowly inject the mixture of spinocain and cerebro-spinal fluid in the syringe, but before the last 1/2 c.cm. is injected, again draw up a few drops of cerebro-spinal fluid and complete the injection. We believe this is better than alternate aspirating and injecting, as in some of the earlier cases in which this was done often ten to twelve minutes elapsed before the operation could be started. Since we have used the technique just described the onset of anaesthesia has been immediate, or, at any rate, as rapid as with stovaine. Prior to the injection the so-called tiltometer is attached to the table, and the degree of tilt necessary can be adjusted.

In the case of an abdominal operation where a mid-line or paramedian incision is being used, the patient is immediately turned on his back. In the case of a hernia, or an operation on an extremity, the patient is kept on his side with the operable site uppermost for five to seven minutes, hemianaesthesia being thus obtained. Spinocain having a lower specific gravity than the cerebro-spinal fluid, the patient lies on the opposite side to the incision, exactly the reverse to stovaine (heavy solution).

Dosage.—We consider that a dose of 2 c.cm. of spinocain, unless the operation be a short one, is inadequate. Dr. Pitkin stated that 400 mg. of spinocain, equivalent to 6 grains of novocain, could be given with impunity, and we have found that anything from 2.5 c.cm. up to 3.2 c.cm., varying with the length of anaesthesia required, the state of the blood pressure, etc., can be given with safety. Our average is 3 c.cm., equivalent to 4½ grains of novocain, and with this amount anaesthesia up to two hours can be obtained, and the onset is also much more rapid.

The Blood Pressure.

According to Pitkin and Kelly,[1] spinocain does not cause any considerable fall in blood pressure, provided sufficient ephedrine is given beforehand. We cannot altogether subscribe to this statement, for in spite of the injection of 50 mg. of ephedrine a very considerable fall may take place. A patient with a systolic pressure of 160 mm. of Hg before the spinal injection is given may, a quarter of an hour afterwards, register only 70 mm. of Hg. According to Hill[2] the fall in blood pressure is very variable, and there may be no fall even in the event of the anaesthesia reaching the second dorsal root. We have not found this so, there being usually a considerable fall, even when the anaesthetic agent reaches the fourth dorsal root.

Kelly states that "if the spinocain is allowed to run up to the second dorsal root, all the vasomotor nerves will be paralysed, and a considerable fall in blood pressure will result." We frequently have anaesthesia up to the nipple level, which corresponds roughly to the fourth dorsal root, and in such instances the fall in blood pressure is very variable, being sometimes great and at other times slight—that is, it may fall as much as 100 mm. of Hg or only 10 or 20 mm. of Hg. Hill suggests that the variability of the fall may be due to the posterior nerve roots only being anaesthetized, and not the anterior, the vaso-constrictors thus escaping. It is difficult to see how this can be when it is remembered that spinocain is lighter than cerebro-spinal fluid. One would expect the solution to float to the surface when the patient is lying on his back, and so to affect the anterior nerve roots as well as the posterior. Suffice it to say that a considerable fall in blood pressure may take place, and certainly the addition of strychnine does not appear to prevent it. We agree with Dr. Hill that "the last word has not been said on this question": it is certainly difficult to explain the variability of the fall in these high anaesthesias.

Undue stress appears to have been laid on the fall of blood pressure. It is usually only transient, being greatest during the first half-hour, and from this period onwards it usually rises slowly, and at the finish may be only little below the original reading. In the event of its falling to 70 mm. of Hg we usually inject another half-grain of ephedrine and lower the head of the table, and this usually causes it to rise slowly. We have not seen any patients become nauseated or restless as a result of lowered pressure, and apart from some pallor of the face they do not seem to be affected to any great degree. It would appear that the toxic symptoms of nausea and collapse, which were at one time attributed to the fall in blood pressure in stovaine anaesthesia, are at least in part due to the much greater toxicity of stovaine; they are certainly absent in spinocain anaesthesia, and there is no reason to fear this early fall in blood pressure.

Controllability of Anaesthesia.

Dr. Pitkin states that if the table be lowered to a 5 degree Trendelenburg position following administration, anaesthesia reaching up to the costal margin will be obtained thereby. We had at first considerable difficulty in obtaining anaesthesia above the umbilicus, sufficient for a simple coeliotomy, following the injection of 3 c.cm. of spinocain, even when the table was placed with the tiltometer at zero. It would appear that to gain anaesthesia up to the fourth or fifth dorsal root the fluid would require to run towards the head—that is, downwards—owing to the convexity of the dorsal spine when the table is level as shown by the tiltometer. This is supposed to be impossible. Dr. Hill states that if 2 c.cm. of spinocain is injected into the lumbar region with the patient in a 5 degree Trendelenburg tilt, "there may be anaesthesia running downwards from an inch below the nipple level; or only from an inch below the umbilicus." We have not found this so; as a general rule we have not been able to get adequate anaesthesia to the costal margin with 2 c.cm. when there has been such a 5 degree tilt.

It was this difficulty that finally induced us to put the patient in the reversed Trendelenburg position and allow the fluid to run up to the dorsal area of the theca. We now give the injection with the patient on his side and with the table in a 7 to 10 degree reversed Trendelenburg position. We have found that 3 c.cm. given thus produces

a perfect anaesthesia with good muscular relaxation sufficient for any abdominal operation. With the adoption of this position for the injection it is important to keep the head and upper cervical area lowered; this can be done with safety by placing the shoulders on a level with the cephalic joint of the table, and by lowering the headpiece. This simply means that during the injection the thorax is raised 7 to 10 degrees, but the head and neck are dropped; and this position, with the head dropped after the patient is turned on his back, is maintained throughout the operation. In the event of a fall of blood pressure taking place, or should the operation require it, the table can be placed level, or even in the Trendelenburg position after ten to fifteen minutes; this does not appear to affect the anaesthesia, the solution being apparently fixed after this period of time. We have not found the controllability to be as accurate as Dr. Pitkin would lead one to believe: in the case of an extremity, however, the anaesthesia can certainly be confined to the lower reaches of the cord by using a sufficient tilt, say 12 to 15 degrees.

Duration of Anaesthesia.

Dr. Hill states that "duration is a variable quantity." Possibly it is, if only 2 c.cm. be used, but if 3 c.cm. be given there is no fear of the anaesthesia passing off under 1¾ hours. Since adopting the reversed Trendelenburg position we have frequently had anaesthesia lasting 2¼ hours, and no case has required general anaesthesia to finish off with.

Comparison with Other Spinal Anaesthetics.

We have had no experience in using percaine or a 10 per cent. novocain normal saline solution. Prior to the introduction of spinocain we have employed Barker's solution of stovaine as a routine. Dr. Howard Jones (*Lancet*, January 25th, 1930, p. 211) seems to be unnecessarily severe in his criticism of the Pitkin method. We have found spinocain to be superior in many ways to stovaine; true, the muscular relaxation may not be so good, but this is more than counterbalanced by the absence of toxic symptoms, so often seen with stovaine, by an increased measure of safety, and lastly by an increased duration of anaesthesia.

Summary.

We regard spinocain as a distinct advance in spinal anaesthesia. Whether the addition of amylo-prolamine is of importance in preventing too rapid absorption of the novocain or not we cannot say; we have certainly found it an ideal spinal anaesthetic which can be given to patients in a critical condition, with little or no fear of a catastrophe. Age does not appear to be any bar, and some of our best results have been in old and enfeebled patients in whom only a local or regional anaesthesia would have been permissible. We regard the most important points in connexion with it to be:

1. A preliminary injection of omnopon and hyoscine half to three-quarters of an hour before the operation.
2. An accurate technique during the spinal injection, which should be painless.
3. Comparatively little mixing of the solution with the cerebro-spinal fluid.
4. For upper abdominal work a 7 to 10 degree reversed Trendelenburg position of the table during the injection.
5. Close attention to the blood pressure readings throughout the operation.
6. Adoption of the Trendelenburg position in the ward for some two hours following upon the operation.

Provided the above details are attended to we are confident that a safe and lasting anaesthesia can be obtained, sufficient for any present-day abdominal operation.

I am greatly indebted to Sir H. A. Ballance for permission to publish these cases, and for his kindly help and criticism of this article.

REMARKS BY SIR HAMILTON BALLANCE.

Additional cases of operation under spinocain and planocain anaesthesia have been performed since the above was written, bringing the total to 50 with uniformly satisfactory results, including a difficult case of renal calculus in an old man. Although novocain has been used for spinal anaesthesia for many years, Dr. Pitkin deserves credit for again directing attention to its advantages and for describing a method of painless administration. In the past I have had many anxious times with such drugs as stovaine, tropacocaine, etc., but there has been no anxiety after administration of the novocain solutions. The hypodermic injection of omnopon and scopolamine about three-quarters of an hour before the spinal injection is a distinct advantage; some patients state afterwards that they do not remember coming into the theatre for the operation. The temporary upward tilt of the thorax ten degrees during the injection, but with the head low by means of lateral flexion of the neck, is recommended if anaesthesia to the nipple line is essential for the operation, and I believe this position to be perfectly safe.

The precise action of novocain on the spinal nerves, motor and sensory, may be a matter for discussion, but I have been impressed with the reliability and controllability of the method, the completeness and duration of the anaesthesia, and the absence of bad after-effects on the patients.

TREATMENT OF EYE DISEASE BY TUBERCULIN.

BY

W. CAMAC WILKINSON, M.D.LOND., F.R.C.P.

THE ophthalmic surgeon is not infrequently faced by cases of inflammatory trouble in the eye which do not yield to ordinary methods of treatment, and in some instances progressively get worse until partial or complete blindness results. I am convinced that in some of these cases the trouble is due to tuberculous disease of the eye, and for the last seven years I have been observing the effect of tuberculin in the diagnosis and treatment of certain refractory cases of chronic conjunctivitis, irido-cyclitis, scleritis, episcleritis, and even some obscure forms of retinitis. Apart from tubercle in the choroid in acute tuberculosis, it would seem that tubercle bacilli may reach the choroid and cause a simple choroiditis.

These tuberculous lesions of the eye have some special characters that have helped to obscure their diagnosis. Like the secondaries of syphilis they occur in the secondary stage, when tubercle bacilli are circulating in the blood; therefore one must not expect any phthisical lesion of the lungs. Examination of the lungs may not help in the diagnosis of tuberculosis of the eye, for these eye diseases are earlier in time than the chronic or phthisical lesions of the lungs. They develop slowly—in the course of years rather than months. They tend especially to recur, and they remain localized; yet in course of time one attack after another causes severe symptoms, and though the lesion is limited, it may give rise to pain, headache, and photophobia, and may greatly impair or destroy sight.

Within the last two or three years I have been given the opportunity of making more extended use of tuberculin, through the interest and co-operation of several ophthalmologists, notably Mr. C. L. Gimblett of the Royal Westminster Ophthalmic Hospital and Dr. Douglas McAlpine of the Middlesex Hospital. The necessary ophthalmoscopic examinations during the progress of treatment were made by surgeons interested in their respective cases. The following notes are of cases that have been referred to me for diagnosis, and for treatment when suitable.

CASE I.

An unmarried woman, aged 31, was described by Mr. Gimblett in June, 1928, as being a case of obscure irido-cyclitis of four years' duration, ending in secondary glaucoma. On incising with the keratome the lens was found to be disintegrated and destroyed. A similar condition has appeared in the left eye, which threatens to go the same way as the right. Tested with

tuberculin by the intracutaneous method the result was positive (++). She was treated with subcutaneous doses, beginning with 0.00001 c.cm. TR. When 0.00006 c.cm. was reached, the temperature was raised to 99.6°, and there was a track reaction (++). In one month there was some improvement, and in January, 1929, Mr. Gimblett wrote: "Patient is very strikingly better, and nothing until she started under your treatment did her the least good. In a few more months she would have been blind. Keratitis punctata has almost disappeared even from the right eye. As to the two anterior chambers, the vitreous chamber is still crowded with exudate." Treatment was continued until 1 c.cm. TR was given in one dose; there was then severe track reaction (+++), but the temperature was only 99.4°. As progress seemed to have come to a standstill, though the patient was very much better from treatment, I proceeded to graduated doses of BE, until 1 c.cm. was given at one dose. The temperature hardly rose above normal. In November, 1929, Mr. Gimblett wrote: "Both eyes quiet and the left vision with a +0.75 D cylinder 80° is 6/18 all. There are deposits on the lens, but no keratitis punctata now. Is there any possibility of her working?" By December, 1929, the patient had gained half a stone in weight and looked a new woman; her eyes were so improved that she hoped to do some work after years of incapacity, and her general health was very much improved.

CASE II.

A girl, aged 16, was treated at Great Ormond Street Hospital for rheumatism at the age of 12, and the heart was thought to be affected; in 1928 it was quite normal. In March, 1923, the eyes became red and painful, and the patient attended the Western Ophthalmic Hospital, where she was treated by Mr. Robinson for seven months, during which time the legs also became inflamed and discharged as the result of erythema induratum. In 1927 the eyes were again affected, and the patient was again treated by Mr. Robinson, being sent to Bournemouth for two months. The eyes became worse and were very painful; there was sharp pain in the head, and the patient was unable to sleep, leeches being applied without benefit. She attended the Ophthalmic Hospital twice a week and had drops instilled. Dr. Douglas McAlpine could find no trace of tuberculosis in the lungs (December, 1927), but sent the patient to the tuberculin dispensary for specific diagnosis. The result was positive, and after prolonged treatment with tuberculin, until very large doses were being taken without any serious reaction, the patient was restored to apparent health. The eyes are now quite normal in appearance and function, and the legs are completely healed. The patient has been back at her usual work (carpet sewing) for more than twelve months.

CASE III.

In October, 1927, a patient was sent by Dr. Carter of Wolverhampton, the symptoms being violent pains in the eyes with photophobia; the eyes were very bloodshot, there was sickness and giddiness, and the temperature was often 99.2° to 99.4° in the evening. The patient was absolutely incapacitated, and was confined to a dark room for many months. The weight was 8 st. 4 lb. Tested with tuberculin (Pirquet method) the reaction was positive. Subcutaneous injections of TAF were given, beginning with 0.0000125 c.cm. The temperature rose to 99.6°. In November the patient wrote: "The sight of both eyes is almost normal now, which is surprising, as the right eye has been short-sighted for several years, and there has been no return of the pain or fear of light that I have had for so many months, and in addition to this I have gained weight—six pounds since I was last weighed in August—so the treatment seems to be eminently satisfactory." In December he wrote again, "The eye is still clear, and it is having quite a normal amount of use." The patient was treated with TAF up to a dose of 0.6 c.cm. (September, 1928); by February, 1929, a dose of 0.95 c.cm. TR had been reached. The weight was 8 st. 9½ lb., and in March, 1929, the patient wrote: "My general health is most satisfactory."

CASE IV.

A married woman, while at the seaside in 1923, had a severe attack of conjunctivitis, the eyes being intensely inflamed, painful, and discharging. They recovered in six weeks; but each summer the sunlight caused recurrence of the inflammation, and dark glasses have been required. In 1928 the eyes were again inflamed and painful, and the vision was blurred; she went to the Central Hospital twice a week for two months, and atropine ointment was applied night and morning. The patient was then almost blind, her vision being gravely distorted. She was seen by Dr. Leech of Watford, who advised that a specific test should be made at the tuberculin dispensary. Her weight was 8 st. 11 lb. At the commencement of specific treatment one eye was completely blind and the other partially so. After treatment with increasingly large doses of tuberculin for eight months the sight became quite keen, and the weight increased from 8 st. 11 lb. to 9 st. 9 lb. In August, 1929, the vision being again impaired, a further course of tuberculin was given. In October, 1929, Dr. Leech wrote. "Her sight is now quite clear and she can read small print, whereas when she started treatment she was unable to see even the largest test-type clearly." Mr. Gimblett wrote: "Evidence of old iritis in right; no keratitis punctata now. Venous engorgement of both discs. Everything appears quiet. No doubt she has had an inflammation of all the ocular structures, even the optic nerves, which is gradually subsiding."

CASE V.

A woman, aged 56, who was sent in July, 1923, by Mr. James of St. George's Hospital, had attended there since 1914 for iridocyclitis. The left eye was blind and the right was gravely affected. She had to be led to the dispensary by her sister, being able to see nothing, not even light. She reacted severely to the intracutaneous test with tuberculin. She was treated at the tuberculin dispensary, the final dose being 1.1 c.cm. TAF. In February, 1929, the sight was so much improved that she could walk through London streets to the dispensary by herself; the general health had also improved. In August, 1929, she could still go about by herself.

CASE VI.

In July, 1928, a female patient with a very bloodshot eye, attributed to ulcers, was given drops and tonics for one month with no improvement; the eye was greatly swollen and red, and she had severe pain. At the Western Ophthalmic Hospital iridocyclitis of eight months' duration was diagnosed. Mr. Taggart suspected tuberculosis, and Dr. Douglas McAlpine sent her to the tuberculin dispensary for specific tests, which were positive. Tuberculin treatment was begun in February, 1929, and the sight is now completely restored; the general health vastly improved, and she "feels a different person."

CASE VII.

A married woman, aged 32, saw Mr. Gimblett in 1925 and was ordered glasses. In October, 1928, she had headaches, and he found retinitis. A blood test was negative. She was sent to the tuberculin dispensary and tested with tuberculin. After a subcutaneous dose of 0.0015 c.cm. T.A.F. the temperature rose to 102°, and the track reaction was ++. She was treated with tuberculin until July 20th, 1929, when with 1.5 c.cm. TAF there was a reaction temperature of 100°. Her improvement was marked, and all pain has been lost since treatment. In April, 1929, Mr. Gimblett wrote: "She has now very much less floating opacities in her right eye and no further fresh patches of retinitis in the left; so far so good."

CASE VIII.

In August, 1928, an unmarried woman, aged 21, complained that her eyes were misty; she could hardly see, and went to the Middlesex Hospital; she attended for three months with no improvement. In November, 1928, she went to the Royal Ophthalmic Hospital and saw Mr. Gimblett, who sent her to the tuberculin dispensary for "double irido-cyclitis of three months' standing." Her weight was 6 st. 7 lb. She was tested with tuberculin, the reaction being +++, and was treated with small doses. In December Mr. Gimblett wrote: "The keratitis punctata has practically disappeared, although both vitreous chambers contain much floating opacities." In March, 1929, he added: "The patient is very greatly improved, and all the keratitis has disappeared. The left pupil is almost fully dilated, and the vitreous is very much clearer." In August, 1929, he wrote: "The eyes are quiet"; and in November, 1929, "The right eye is well; I think the left eye has no keratitis punctata, and apparently no active lesion." In January, 1929, after an absence of fifteen months, the patient returned to work (fine needlework). Her weight was 6 st. 12 lb., a gain of 6 lb. and the general health had greatly improved. She is extremely sensitive to tuberculin, and still needs treatment for a long time.

CASE IX.

In a married woman, aged 44, the right eye was affected at the ages of 25 and 28. In February, 1929, she visited the Western Ophthalmic Hospital, where the eyes were reported weak, and reading glasses were ordered. Six weeks later she had an operation on the left eye, followed by complete loss of vision. She was advised by Mr. Taggart to attend the Hospital for Epilepsy at Maida Vale, where she saw Dr. McAlpine, who sent her to the tuberculin dispensary. The eye was still blind and very painful. A tuberculin test resulted in a reaction of +++, and a course of treatment was begun in May, 1929. In July there was less pain, and the sight was clearer. In August the eye was weak again, and there was pain and inflammation; a fortnight later the eye was much better; the discharge had ceased, and the eye was clearer than before. The sight is now so much better that she can read, and her general health is excellent. The treatment has been uninterrupted in spite of relapse. In December, 1929, she reached the highest dose so far, 0.5 c.cm. TAF; the treatment is still continuing.

Four other patients who were sent to the tuberculin dispensary for diagnosis gave negative reactions both to intracutaneous and to subcutaneous tests, showing that it

is far from true that all persons react to tuberculin. In these cases tuberculin treatment was not undertaken.

The cases I have recorded above seem to offer prima facie evidence that there are patients with inflammatory trouble in the eyes who do not benefit by ordinary methods of treatment; that many of these patients react to diagnostic doses of tuberculin; and that treatment with tuberculin produces marked improvement, or even arrest of the trouble, in a considerable number of these reacting patients. Since the use of tuberculin, for both diagnosis and treatment, by the methods I advocate is completely innocuous to the patient, I submit that its employment in such cases is amply justified. The satisfaction of the patients who have been treated at the tuberculin dispensary, coupled with the recorded opinions of the ophthalmic surgeons under whose care they were, encourage me to suggest that wider trial of these methods should be made in the treatment of eye diseases.

ON SPECIFIC ANTITOXINS IN STREPTOCOCCAL INFECTIONS.

BY

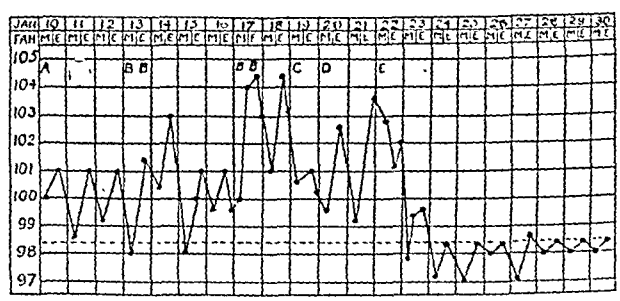
HERBERT H. BROWN, M.D., F.R.C.S.,

CONSULTING SURGEON TO THE EAST SUFFOLK HOSPITAL.

WHILE it has long been common knowledge that streptococcal infection was responsible for a number of clinical varieties of disease—for example, cellulitis, erysipelas, tonsillitis, puerperal fever, scarlet fever, ulcerative endocarditis, etc.—it is only in recent years that it has been possible to differentiate and classify special groups of streptococci.

It was found that streptococci could be differentiated by their fermentative action on different sugars, and also by their haemolytic action on blood corpuscles, certain streptococci when grown on blood agar plates producing a clear red halo of haemolysis around each colony. These haemolytic streptococci are of special importance, as they are responsible for some of the most serious infections—for example, puerperal septicaemia, erysipelas, and scarlet fever. In 1924 the Dicks described a soluble toxin, derived from culture of haemolytic streptococci obtained from the throats of scarlatinal patients, and with which experimental scarlet fever had been produced. This toxin when injected intradermally produces a pronounced erythematous blush in the surrounding skin of patients whose blood does not contain enough of the specific antitoxin to neutralize it, and is widely used to test susceptibility to scarlatinal infection (the Dick test), exactly in the same way that the diphtheria toxin is used to test susceptibility to diphtheria (the Schick test).

Similar toxins were discovered in 1926 by Birkhaug in the case of erysipelas, and by Lash and Kaplan in the case of puerperal sepsis, the toxin of which differs from the Dick scarlatinal toxin in being heat labile, whereas the Dick toxin is not destroyed by boiling. These toxins also produce skin reactions similar to those of the Dick reaction in persons susceptible to erysipelas and puerperal fever respectively. The toxin prepared by Lash and Kaplan was made use of for testing the susceptibility of pregnant and non-pregnant women to puerperal sepsis. Antitoxic serums were produced by Birkhaug by immunizing animals with erysipelas toxin. This serum agglutinated haemolytic streptococci from erysipelas, and also had a striking therapeutic effect in erysipelas infection. Similar antitoxins have been prepared from toxin from puerperal septicaemia. Some doubt, however, has been thrown on the specific nature of these toxins and antitoxins during the last few years, especially by some investigators in this country. It would appear probable that there is a factor common to all three groups, that there is also a factor special to each of the toxins and antitoxins, and that to produce the most satisfactory therapeutic effect the specific antitoxin should be injected.



With regard to the specificity of the scarlet fever and erysipelas toxins, the Dicks have lately conducted a series of experiments which should be conclusive.[1] They demonstrated that there was no direct relation between spontaneous immunity to scarlet fever and erysipelas toxin. It was shown that an attack of scarlet fever does not confer immunity to erysipelas, and that artificial immunization by scarlet fever toxin confers no immunity to erysipelas toxin; also that scarlet fever antitoxin prepared by immunizing a horse with toxin from scarlet fever streptococcus neutralizes scarlatinal toxins, but does not neutralize erysipelas toxin, and erysipelas antitoxin neutralizes toxins derived from strains of erysipelas streptococci, but not scarlet fever toxin. The Dicks conclude, therefore, that the soluble toxins produced by scarlet fever and by erysipelas haemolytic streptococci are immunologically specific and distinct.

Working with scarlet fever, erysipelas, and puerperal fever toxins, and with convalescent serums and antitoxins, Ferry and Fisher found that in low dilutions of the serum there was more or less cross-neutralization of the toxin by the serum, but in high dilutions the serums neutralized only their homologous toxins. If these results are accepted it is evident that to get the fullest advantage from antitoxic treatment the special antitoxin should be employed. In the case of puerperal fever, although the great majority of severe infections are due to the haemolytic *Streptococcus pyogenes*, other organisms are occasionally responsible, and a culture from the cervical canal and from the blood should be taken.

A case which has recently been under my care is a very striking illustration of this specific action.

The patient was attacked by a throat infection with a haemolytic streptococcus, which in the course of two or three days from the beginning of the illness invaded the middle ear and the mastoid cells on the right side. I saw her on the third day; her evening temperature was 101° F., and there was tenderness and slight oedema over the mastoid. A swab from the throat was taken, and 10 c.cm. of polyvalent antistreptococcal serum administered. On the following day an operation was performed upon the mastoid by Mr. K. D. Mackenzie. All the mastoid cells were infected, and a pure culture of a haemolytic streptococcus was obtained. The throat culture showed haemolytic streptococci and *Micrococcus catarrhalis*. The culture was incubated with the patient's blood by Dr. Biddle, pathologist to the East Suffolk Hospital, and the blood was found to have no bactericidal effect upon the streptococcus.

Following the operation there was free suppuration, and the temperature showed no diminution, reaching 101° F. each evening. On the fourth day after the operation 10 c.cm. of concentrated scarlet fever antitoxin was given intramuscularly in the morning, and the injection was repeated in the evening. On the following

A, Operation. B, 10 c.cm. scarlatinal antitoxin. C, 10 c.cm. polyvalent serum. D, 15 c.cm. collosol argentum (intravenous). E, 10 c.cm. erysipelas antitoxin.

day, the fifth after operation, the temperature reached 103° at 2 p.m., and definite erysipelatous infection of the pinna of the ear and the skin in the temporal fossa was evident. The pulse rate went up to 110; it had previously ranged between 80 and 100. The leucocyte count was 13,000.

During the next few days the erysipelas continued to spread in the skin of the forehead to the nose. On the eighth day after the operation the temperature was 104° in the morning and 104.4° in the evening; the pulse rate was 116. The patient was given 10 c.cm. of scarlatinal antitoxin intramuscularly in the morning, and a similar amount in the evening. On the next day the temperature was 101° in the morning and 104° in the evening. On the tenth day the temperature was 101°, and 10 c.cm of polyvalent streptococcal serum were adminstered. The leucocyte count was 10,000. On the eleventh day erysipelatous infection had reached the left side of the face. The temperature was 102.6°, and 15 c.cm. of colloidal silver was given intravenously. No improvement followed, and on the thirteenth day the temperature again reached 103° F. An intramuscular injection of 10 c.cm. of concentrated erysipelas antitoxin was given on that afternoon.

On the next morning the temperature fell to 98°, only reaching 99.4° in the evening, and on the following and subsequent days it remained absolutely normal. All traces of erysipelas had disappeared from the face, the leucocyte count dropped to 7,000, and the patient looked and felt completely convalescent. Suppuration rapidly diminished, and completely disappeared in a fortnight.

The improvement in the patient's condition was remarkably dramatic, and I think undoubtedly due to the specific action of the erysipelas antitoxin on the streptococcal infection.

PSITTACOSIS WITH ENCEPHALITIC SYMPTOMS.

BY

HENRY J. KRICHEFSKI, M.B., B.S.LOND.,

RESIDENT MEDICAL OFFICER TO THE BRITISH HOSPITAL, PORT SAID.

DR. A. P. THOMPSON (*Lancet*, February 22nd, 1930, p. 396) describes a case (No. 8) of psittacosis in which the nervous symptoms were marked enough to suggest a diagnosis of encephalitis. Below is a description of a similar case occurring in Port Said. This is the first recorded case of the disease in Egypt.

The patient, Mrs. H., aged 32, a British resident of Port Said, had begun to feel ill on the evening of February 10th, 1930, with headache, cough, and vomiting. She was seen by a local practitioner, and as her condition became steadily worse during the next few days and no definite diagnosis could be arrived at, she was admitted to the British Hospital on February 15th.

On admission the patient looked ill, being flushed and bathed in perspiration. She complained of severe headache, especially at the back of the head, and difficulty in speaking and swallowing. She was also slightly delirious. Her temperature was 102.8° F., pulse rate 114, and respiration rate 28. On examination a few moist sounds were heard at the left apex. The right lung was clear and the heart normal. The abdomen was distended, but not tender on palpation, and the tip of the spleen could just be felt. A trace of albumin was present in the urine. A bilateral Babinski response was elicited, and also Kernig's and Brudzinski's signs. Both knee-jerks were absent, and the fundi were normal. There was no cough or dyspnœa, and no sputum could be obtained.

On February 16th the patient's condition was worse, the temperature being 104° F. and the pulse rate 98. She was still complaining of severe headache. Lumbar puncture was performed; the fluid was clear and not under pressure and it disclosed no abnormalities on examination. On February 17th she was much worse; the abdominal distension had increased, the temperature was 102.6° F., and the pulse rate 88. The left apex was now solid and air entry was practically absent. Coarse crepitations were present over the whole of the left chest. The patient was more delirious, very weak, and unable to speak.

Agglutination tests for "O" and "H" agglutinins against *B. typhosus* and *B. paratyphosus* A and B were negative, and it was not possible to demonstrate the presence of specific agglutinins for any member of the biphasic group of salmonella organisms. Blood culture in a variety of media and inoculation experiments were negative. Culture of the fæces and urine resulted in the isolation of *B. faecalis alkaligenes*. It was present in pure culture in the urine. Thompson notes a similar finding in one or two cases. There was a leucocytosis, the number of white blood corpuscles being 15,000 per c.mm.

During the evening of February 17th the patient was seen by another medical man in consultation, and a diagnosis of psittacosis was made. The patient had twenty-three birds at home including three parrots and two love-birds recently acquired. The husband stated that some of the birds had been fighting furiously. Two had died after this disturbance; probably they had been sick and were killed by the others. All the birds were gassed, and post-mortem examination and a fairly extensive cultural investigation yielded negative results. This does not discount the possibility of the dead birds having been infected with the virus.

During the next three days coma supervened; the abdomen became more distended and the temperature remained between 103° and 104° F., the pulse being relatively slow. Examination of the fundi showed blurring of the edges of the discs, suggesting a rise of intracranial pressure. The condition of the patient was critical. On the evening of February 21st lumbar puncture was again performed; the fluid was clear, but this time it came out under great pressure, and on examination small numbers of diplococci were seen. The same evening an injection of 30 c.cm. of polyvalent antipneumococcal serum was given intrathecally. After a rather severe reaction the temperature fell the next day to 100.2° F. A further 20 c.cm. of the same serum were then given, intrathecally as before. A mild reaction occurred, during which the temperature rose to 102° F. and then fell to 99° F. The coma now began to diminish, and the patient seemed much better. The fundi were now normal.

On February 23rd 20 c.cm. of polyvalent antimeningococcal serum were given intravenously, and the temperature fell to 98.2° F. in the next few hours. During the following two weeks the patient slowly gained ground and made an uninterrupted recovery. On March 5th she was able to sit up in bed and take solid nourishment. At the moment of writing she still has some slight difficulty in articulation, and the features are rather inexpressive, resembling the mask-like facies seen after encephalitis lethargica. However, both these conditions are improving rapidly, so that in all probability no permanent disability will result.

I have never seen any reference to a case of psittacosis in which the meningeal symptoms and the general nervous symptoms were so pronounced. Although an apical lobar pneumonia is always associated with active delirium and some nervous symptoms, I incline to the clinical diagnosis of psittacosis, for these reasons:

1. After a week's illness the patient appeared to be as ill as if she were in the third week of enteric fever—she had a brown, furred tongue, sordes on lips, etc.

2. The left lung was solid: there was no tubular breathing and hardly any air entry; the patient had no dyspnœa, no cough and no expectoration: coarse crepitations were present: in fact, the chest condition was more acute than in any condition I know.

3. A meningitis can develop in any acute condition.

4. The specific serum treatment was hardly sufficient to have worked so remarkable a cure.

5. The nervous symptoms were more those of an encephalitis than of a pure meningitis—for example, the mask-like expression of the face, the early loss of knee-jerks, the double Babinski response, and bulbar paralytic symptoms (speech and swallowing) before the cerebro-spinal fluid was even cloudy or contained abnormal cells or organisms.

6. The impression I gained from this case was that it was a clinical syndrome that I had never met before.

I am indebted to Dr. Dolbey and Major Benstead of Cairo for their kind and valuable assistance in enabling me to prepare this case for publication, and to Dr. R. P. Stewart for permitting me to publish this report.

TREATMENT OF MEASLES WITH AMIDOPYRIN.

BY

J. I. COLLIER, PH.D., B.SC.LOND., M.R.C.S., L.R.C.P.,

FORMERLY ASSISTANT, BIOCHEMICAL DEPARTMENT, MIDDLESEX HOSPITAL.

THESE observations are intended as a preliminary communication on the curative effects of amidopyrin in the treatment of measles. This drug is a white crystalline compound, slightly bitter, and easily soluble in water. According to the French *Pharmaceutical Codex* the maximum single dose is 15 grains, the maximum in twenty-four hours is 45 grains.

In the following case of measles drastic measures seemed to be indicated, and I decided to utilize the powerful antipyretic property of the drug. The discovery that it seemed to exercise an almost specific action on the disease itself was fortuitous, and led me to make a search of the literature. I found that Loewenthal[1] had used the same drug in the treatment of measles, but it does not seem to have been generally adopted.

The patient, a girl aged 8, had a history of whooping-cough in 1922, leaving her with chronic bronchitis. In September, 1929, she had lobar pneumonia, and while convalescing, though still weak and coughing, she developed measles. I was called to see her one afternoon when the rash was just appearing behind the ears and on the forehead. Her temperature was 104.5°; there was marked coryza, and Koplik's spots were present. The pre-existing cough was more severe. She was immediately put on amidopyrin, 5 grains four-hourly day and night. The next morning (about twenty hours after she was first seen) the temperature was down to 100°. Instead of the anticipated profuse eruption only a faint morbilliform rash was showing. The drug was continued

for forty-eight hours. Improvement was rapid, and in four days after the onset of the rash the patient was feeling quite well and able to get out of bed. The cough was almost gone and indeed was less intense than it had been before her attack of measles.

In view of this result, which confirmed Loewenthal's findings, I decided to make further investigations, and administered amidopyrin in twenty-six cases. The drug was given in the form of pyramidon crystals, the appropriate dose being administered in a teaspoon with a little water. In all cases twelve powders were given at four-hourly intervals during the day and night. Even infants took the drug easily. Comparatively large doses were used according to the formula:

$$\text{Dose (to nearest grain)} = \frac{\text{Age}}{\text{Age}+12} \times \text{maximum dose of drug (gr. 15)}.$$

The doses given were 2 to 5 grains.

Results.

It must be stated at the outset that it was impossible to obtain accurate statistics in general practice, especially in the poorer districts of London, where this work was carried out. In some cases a doctor is called in only to make a diagnosis and in other cases only when the patient does not seem to be progressing well. In view of the special treatment patients were visited more often than is usual in such cases, though a number of parents had to be persuaded to allow this to be done. In the series of cases reported six were seen twice a day during the course of the illness, fifteen were seen once daily, and five only twice with an interval of a few days. It follows that the results can only be recorded in general terms, but, even so, the results are remarkable.

It may be taken that an average case of measles as seen in general practice is quite well and able to get out of bed in ten to twelve days, a slight cough usually persisting even for a week or two longer. This will be taken as a standard with which to compare these cases treated with amidopyrin. These are divided into three groups, according to the time of administration of the drug in relation to the onset of the disease.

Group 1 consists of five cases, contacts from another member of the family, who were specially watched for the onset of the disease, and were treated during the invasion stage on the appearance of Koplik's spots. The measles did not develop in these cases; in only two was there a suspicion of a rash. The children were put to bed as a precaution, but were quite well in two days.

Group 2 consists of sixteen cases seen at the onset of the rash. This is the largest group, the stage at which most cases are first seen in general practice. The administration of amidopyrin caused immediate reduction of temperature, and all symptoms cleared rapidly. The patients were quite well in three or four days.

Group 3 consists of five cases seen at various late stages of the disease in which the drug had a beneficial but less striking effect.

A marked feature of the drug treatment was the fall in temperature within the first day and the complete clearing up of the cough. No complications were observed. The impression conveyed by these results was that the drug must be given early in the disease, and if given early enough in the "Koplik's spot" stage the disease is even aborted.

Criticism.

These results are open to criticism in several directions. It may be argued that the cases treated were mild cases of measles which would have shown almost the same results had no special treatment been given, for it is well known that epidemics of measles vary much in intensity and such mild cases are not uncommon. It might also be argued that many of the cases were not measles, but were diagnosed in error.

This investigation was carried out in the borough of Stepney, where it is interesting to note there were sixteen deaths from measles in February, 1930. In order to obtain a full investigation, necessitating observations at regular short intervals, and confirmation of diagnoses by fever specialists, the medical superintendent of the Eastern Fever Hospital was approached on the subject. Dr. Ronaldson of the staff of this hospital agreed to carry out treatment in six cases of measles on the lines described. Cases at various stages of the disease were chosen, and these were treated and re-examined three days later. The results were considered so satisfactory that it was decided to try the method on a large scale with observations at four-hourly intervals. The results of this investigation will be published in due course. It should, however, be pointed out that measles is not isolated in hospital. The cases are usually treated at home and only sent to hospital when complications are setting in. It follows that hospital cases of measles are usually late cases.

Conclusion.

Amidopyrin has a striking curative effect on the course of measles. The disease may be completely aborted if treatment is given early enough. This treatment is specially suited to general practice, where the disease is seen at its earliest stage.

I am indebted to Dr. Ronaldson of the Eastern Fever Hospital for his help and suggestions in this paper.

DESTRUCTION OF TONSILS BY DIATHERMY.

BY

WARNER COLLINS, M.D., B.Sc., D.M.R.E.,

HONORARY RADIOLOGIST TO ST. JAMES AND THE WEIR HOSPITAL, LONDON.

IT is well known that many patients with diseased tonsils cannot be subjected to surgical treatment on account of fear or age, or some condition rendering them more liable than the average person to surgical shock. Until treatment by diathermy was introduced the only forms of physical therapy for these patients were by x rays, radium, or the simple electric cautery. X rays and radium cause the tonsils and lymphoid tissue to diminish in size, but the remaining shrunken fibrous tonsil may continue to serve as a focus of infection. Haemolytic streptococci and other pathogenic organisms have repeatedly been found in tonsils that have been subjected to treatment by x rays and radium. Moreover, such treatment may produce dermatitis, and damage to the thyroid and parathyroid glands or neighbouring structures. The effects of the simple electric cautery do not reach the depths of the tonsil, and the hot metal moving through the tissues may damage blood vessels enough to bring about the possibility of secondary haemorrhage.

The inadequateness of other methods affords special reason for examining the possibilities of treatment by diathermy. Diathermy apparatus has undergone steady improvement in design, and side by side with this improvement has accumulated a considerable experience of its use. In this country, in America, and on the Continent, the value of diathermy as a technique for the treatment of lesions of the throat is now pretty generally accepted. During the past four years I have combined true diathermy with fulguration. The tonsil is first killed by the production in its substance of heat, which almost immediately causes coagulation of the proteins and boiling of the tissue fluids. This is true diathermy coagulation. Next I deliberately arc from the tonsil with the active ball electrode, in order to seal the smaller blood vessels and lymphatics, and this process is as efficient as surgical ligation. As a preliminary measure it is often advisable to estimate the blood coagulation time and to consider whether the patient is in a fit state for tonsillectomy. I mention this precaution as I once escaped disaster by refusing to treat a patient who some hours later developed influenzal pneumonia. A general anaesthetic is not required; the use of ether would be dangerous, as a mixture of ether and air might easily be exploded by the sparking of the machine. I prefer cocaine spray anaesthesia, using 1½ to 2 grains of the hydrochloride dissolved in 2 drachms of water.

It is necessary to work with a temperature between 60° C. and 100° C., and this is a predetermined constant for the particular controls of the machine when an indifferent lead electrode 8 × 6 × 1/16 in. is used. This electrode, bearing a suitable terminal, is covered with four

thicknesses of lint, saturated in 20 per cent. saline and strapped securely to one wrist. There is no advantage to be gained from multiplying the number of indifferent electrodes. The active electrode is usually a small metal ball mounted on a curved ebonite holder, through which the insulated current is carried. It is well to keep a variety of electrodes for special sizes and situations of the tonsils. A diathermy current of two amperes is adequate, the frequency of oscillations being about 500,000 per second. The surgeon depresses the patient's tongue with a glass spatula, and uses a forehead spotlight illumination; he should not switch on the current until the active ball electrode is in contact with the tonsil tissue. The operation is rapidly effected with the patient sitting in a comfortable chair. During the operation the tonsil becomes rapidly hotter and a coagulation area spreads from the point of application of the ball electrode to the outer surface generally. The entire operation takes but a few seconds, and the ball electrode is withdrawn to allow sufficient arcing effectively to seal the smaller blood vessels. After the operation the patient is told to use an antiseptic mouthwash three times a day, and not to gargle. A suitable throat tablet—for example, of benzoic acid, cocaine, eucalyptol, and menthol—is prescribed, and for three days the patient should take a light diet. During the first twenty-four or forty-eight hours the tissue round the tonsil becomes oedematous. The patient has only slight discomfort, but as in some cases there is a rise of temperature I think it is advisable to order rest in bed for forty-eight hours. Surgical shock does not occur. Coagulated tissue starts to separate as a slough in about three days, and the process continues for a week or a fortnight. The odour of the slough, though slightly disagreeable, does not trouble the patient, and it disappears when the slough has separated. Infection has not occurred in any of my cases. The formation of scar tissue is accompanied by an ingrowth of epithelium, and the resulting scar is soft and glossy, and shows practically no sign of contraction. I know of no case in which secondary haemorrhage has occurred.

In diathermy the heat is generated within the tonsil and surrounding tissue; in contrast, therefore, with treatment by means of the electric cautery, where the effect is limited to a narrow zone around the hot metal, the tonsil is treated as a unit. In tissue subjected to cautery treatment the proteins are broken down into products responsible for causing toxic shock, the coagulated protein produced by diathermy has no such effect.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CYST OF THE EPIGLOTTIS.

THE following case of dysphagia associated with cyst of the epiglottis is interesting, because the dysphagia persisted after the cyst had been removed.

The patient, a very emaciated woman aged 64, had been seen once by Dr. Masterman-Wood, who sent her to me with the following report: She had come to him complaining that in the past twelve months she had had difficulty and increasing pain in swallowing; regurgitation of food, an associated symptom, produced cough and dyspnoea. By indirect laryngoscopy Dr. Masterman-Wood had recognized an abnormality of the epiglottis, and on account of this he referred the patient to me at the Torbay Hospital. I made a laryngeal examination on January 8th, and found a large globular swelling with blood vessels passing over its surface, situated in front of the left half of the epiglottis and obscuring the left vallecula.

The patient was admitted to hospital on January 23rd, and on the following day, using general anaesthesia, I passed a Jackson's direct laryngoscope, and found that the swelling had a narrow base and was attached to the anterior surface of the left half of the epiglottis. By means of Paterson's laryngeal forceps I grasped the swelling, but being cystic it ruptured, and thick viscid secretion escaped. The site of the cyst was then mopped dry, and I removed all visible remains of the cyst wall by means of the forceps. A diathermy terminal was now passed through the laryngoscope down to the raw area from which the cyst had been removed and the current was applied by Dr. B. Halliwell.

The pathologist's report on the cyst wall was as follows:

"The tissue consists of squamous epithelium forming a layer over young fibrous tissue. The histological appearances are quite consistent with the cyst being dermoid. There is no suggestion of any malignant growth."

The patient was discharged from hospital on January 23rd. She still complained of difficulty in swallowing, and the site of origin of the cyst was incompletely healed. On February 10th she came to the out-patient department; the difficulty in swallowing was still present. Indirect laryngoscopy showed that the affected area was completely healed, and that there was some contraction of the left lateral glosso-epiglottic fold. The patient was instructed to return to the hospital if the dysphagia persisted, but so far she has not appeared. She showed no relief at being told that the condition was non-malignant. It is difficult to explain the continuance of the dysphagia after the site of the cyst had healed.

Honorary Laryngologist, Torbay Hospital.

ACUTE DILATATION OF THE STOMACH.

THE following details of a case of acute dilatation of the stomach seem to be worth recording in view of the rarity of such a rapidly fatal termination after taking a single large meal.

I was called early one morning to see an Indian labourer, aged about 23. The history was that he became suddenly ill some time during the previous night, about six hours before my arrival. He said he had attended a dinner that night, and had eaten a large quantity of food. He was vomiting enormous quantities of yellow fluid, was in great pain, and could not swallow anything. On examination, he was found to have a subnormal temperature and a distended abdomen, and he exhibited all the signs of collapse. On percussing the stomach, its lower border could easily be made out about three finger-breadths above the pubis, and the stomach note could also be elicited for about the same distance to the right of the middle line. He also had intense pain all over the abdomen, but no rigidity could be made out. The vomited matter had a sour smell; it contained a few grains of rice, of which article the patient had partaken liberally. He was very restless and, though placed in the knee-elbow position, he obtained no relief. He was ordered to hospital, but died on the way.

The patient was well nourished and muscular, and no evidence of any organic disease was discovered at the necropsy. The stomach was found to extend as low down as two inches from the symphysis pubis, and was very congested. The arteries stood out prominently, and the duodenum was also dilated. On slitting open the organ it was found to contain only some bile-stained fluid. Death was undoubtedly due to the acute dilatation of the stomach.

THIRD NERVE PARALYSIS AFTER MUMPS AND CHICKEN-POX.

PARALYSIS of the intrinsic muscles of the eye after diphtheria is sufficiently common, but it is not often that a similar condition is seen following other infective diseases.

Some three years ago a child was admitted to the eye ward of the Coventry Hospital suffering from paralysis of the sphincter of both irides and from loss of accommodation. Her food returned through her nose, showing that the palatal muscles were paralysed. In fact, the child showed the complete picture of post-diphtheritic paralysis. There was no history of a sore throat, and a swab from nose and fauces was negative. After some questioning a history of mumps was obtained, which had affected several members of the family. The patient was transferred to the medical wards and rapidly made a complete recovery. Unfortunately I have lost sight of the case and cannot trace the notes.

Recently Dr. O'Connor of Leamington asked me to see a girl, aged 15, who was just recovering from varicella. She still had pustules on her face and body. I found that she had a complete paralysis of the sphincter iridis of both eyes, causing the pupils to be fully dilated. Accommodation was also paralysed. In this case the palatal muscles were not affected. Six weeks later she could read ordinary print without glasses, there was no paralysis of accommodation, and the pupils were nearly normal in size and reacted to light and accommodation.

Reports of Societies.

OSTEOGENESIS IMPERFECTA.

AT a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on May 30th, Mr. H. A. T. FAIRBANK delivered his presidential address on osteogenesis imperfecta.

Mr. Fairbank remarked that the condition of bone fragility had been burdened with a multitude of names, some of which were now recognized as misleading. He preferred the term "osteogenesis imperfecta" because it was descriptive, and in this country was the name by which the disease was most commonly called. It was applied to the infection met with in infants and children in which the chief feature was fragility of the bones. Cases were usually divided into those in which fractures occurred before birth, and those in children who were apparently healthy when born, bone fragility being only evident at a later date; there were many reasons, however, for believing that in the second group as well as in the first the affection began in intrauterine life, and Mr. Fairbank believed it was always congenital. Bone fragility and sclerotics of a deep blue tinge might occur together or separately in members of the same family; many instances of such families had been recorded. Of twenty-eight cases in which he had been able to collect radiographic and other details, familial or hereditary influence was evident in eight. Of the thirteen in which the first fracture was known to have occurred at or before birth there was only one in which the affection appeared in another member of the family, and that was a post-natal case. Of the fifteen post-natal cases in this series many sustained their first fractures soon after birth, and might well be reckoned as ante-natal cases of mild severity. The association with blue sclerotics was seen in eleven cases, four of which were ante-natal. So many infants had blue sclerotics that it was necessary to limit the term to cases in which the blueness was definitely marked. The cases might be divided into the thick bone type, and the disease, a and fragile bone type. The features of the first appearance re best seen in a severe case soon after birth. these cases; long bones were short and, usually, broad and children were puey showed one or more fractures, with a two days. us formation. Massage had been recommended for the limbs, but this had to be practised with the very greatest care. Faradic treatment of the muscles should be more helpful if the children could stand it; this was a rational treatment, for it seemed hopeless to expect much solidification of the bones without some preliminary treatment of the muscles. In the speaker's experience it was rarely possible to pull out the limb shortened by a malunited bone, and to maintain the length for the many weeks necessary. It was therefore of paramount importance to preserve, if possible, accurate alignment from the first when treating a fracture, for if any bowing was allowed to occur the chance of re-fracture was increased. The only way to deal with a case of marked deformity was to abandon all efforts at lengthening the limb, and if, after due consideration, it was thought advisable to operate, the bone should be supported by overlapping the fragments so that perfect alignment and fixation could be maintained with ease. His operative experience in this condition was limited; he had treated only five cases, but he could not help feeling that the right way to operate for correction of the deformity was to sacrifice lengthening of the bone in order to obtain, instead, a perfect alignment.

PAGET'S DISEASE OF THE BREAST.

A MEETING of the Section of Pathology of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on May 9th, with the president, Dr. J. LAIT, in the chair. Dr. A. B. CLERY showed specimens from cases of Paget's disease of the breast.

The PRESIDENT said he had seen two cases of Paget's disease, neither of which resembled either of the specimens shown by Dr. Clery. In one of his cases the nipple had completely disappeared owing to ulceration, and in the other case there was discharge from the nipple. On reading Professor Muir's paper on Paget's disease in the *Journal of Pathology* he had been surprised to find that some of his own sections resembled very closely some in that paper. One of Professor Muir's cases showed very clearly intraduct carcinoma; this had appeared markedly in one of his own cases. On examining the nipple large swollen cells were found which were quite obviously not part of the squamous epithelium. He thought that in Paget's disease there was an example of duct cancer spreading into the skin.

Dr. T. T. O'FARRELL thought the first case described by Dr. Clery was one of epithelioma; he did not regard the second case as malignant. He mentioned a case he had recently seen in which the nipple was full of cancerous growth; this was not a cancer of the nipple, but a cancer of the breast involving the nipple. He divided these cases into three groups: expected early malignancy, true early malignancy, and established malignancy.

Dr. CLERY, replying, said that the first specimen showed fairly well Paget's cells situated deep down in the Malpighian layer; these were large cells with dropsical protoplasm, and rather deeply stained nuclei. He believed that 1 per cent. of cases of cancer of the breast followed Paget's disease, which he considered as a clinical entity. Epithelioma could occur in the nipple as anywhere else, but he did not think that such an epithelioma was Paget's disease. He was inclined to conclude that his first case exhibited the characteristics of a duct cancer.

Malignant Disease of the Thyroid.

Dr. A. HALPENNY showed a specimen from a case of malignant disease of the thyroid gland with formation of secondaries.

The patient was a woman, aged 21, who was admitted to hospital on September 23rd, 1929, and died on October 15th. A swelling which corresponded with the position of the thyroid gland was stated to have appeared three months previously. The patient complained of huskiness, but there was no tremor and no exophthalmos, and the urine was normal; the enlarged thyroid was found to be smooth and firm, but not hard. She developed marked dyspnoea, and on October 3rd part of the right lobe of the thyroid gland was excised. A week later she became pyrexial, and the temperature reached 103° F. on the day before she died, apparently from asphyxia, fourteen days after the operation. At the necropsy the thyroid gland was found to be nodular and

enlarged; secondary growths of small nodules appeared in the larynx and the trachea. There was gross enlargement of the mediastinal glands, and numerous secondary nodules were scattered throughout the lungs.

The PRESIDENT raised the question of frequency of cancer of the thyroid gland; he thought that it was not very common. He had only once performed a post-mortem examination on a case of malignant disease of the thyroid. He believed that cancer of the thyroid spread most frequently to the lungs. Dr. A. B. CLERY said the patient was suffering from very profound dyspnœa. The advisability of tracheotomy was considered, but the idea was abandoned. He thought the clinical question was whether the dyspnœa was due to heart failure and œdema of the lungs, or to pressure on the trachea. Dr. A. HALPENNY, replying, said there was no evidence of metastasis in the bones, and nothing in the clinical history to suggest it. The incidence of malignant disease in tumours of the thyroid gland was about 1 per cent.

Cerebral Thrombosis and Aneurysm.

Dr. A. R. PARSONS showed two brain specimens. The first was taken from a woman, aged about 60, who was admitted to hospital complaining of some difficulty in articulation. When Dr. Parsons saw her early in September, 1929, he could find nothing wrong with the movement of lips, palate, or tongue, but gradually impairment of movement of the tongue came on with partial paralysis of the pharynx; then difficulty in swallowing set in, and paralysis of the right third nerve. The patient died on September 23rd. Until the paralysis of the third nerve developed the case looked like an ordinary acute paralysis of the pharynx, tongue, lip, and larynx. The second specimen was taken from a patient, a woman aged 47, who had been found unconscious in her bathroom, foaming from the mouth; on admission to hospital she was thought to be suffering from an attack of cerebral haemorrhage. Her sister said that since the age of 14 she had been liable to attacks of *petit mal* at each menstrual period. All the limbs seemed to be equally affected, but there was no distortion of the face. She gradually improved, and seemed to be nearly well. A Wassermann test was negative; her systolic blood pressure was 137, and the diastolic was 95, there was a trace of albumin in the urine. After thirteen days she was peculiar in her manner, and suddenly became unconscious. A spinal puncture was performed, but only pure blood came away. A large haemorrhage, probably at the base of the brain, was suspected, and she died in twenty-four hours.

The PRESIDENT, demonstrating the first specimen, said there was unilateral thrombosis of the pons and medulla. In the second specimen the brain showed miliary aneurysm in the circle of Willis, and extensive haemorrhage. He asked if a Wassermann test had been performed in the first case described by Dr. Parsons, and said that these thrombosis cases were usually syphilitic.

Dr. A. B. CLERY said it was difficult to realize how a sufficient degree of trauma could occur without producing a fracture. He thought the transient diplopia in the aneurysm case might have been due to third nerve paralysis. Dr. A. HALPENNY mentioned the possibility of the patient's peculiar behaviour in the second case being due to a lesion somewhere else, perhaps in the frontal lobes, and asked if Dr. Parsons believed that aneurysms of the circle of Willis were very seldom due to syphilis; in America it was thought that only about 5 per cent. of them were due to syphilis. Dr. G. C. DOCKERAY asked Dr. Parsons if his second case was not really a congenital cranial aneurysm. Dr. T. T. O'FARRELL said that the site of the aneurysm was unusual. The lesion in the first case was very extensive, involving the crus, pons, and cerebellum. It was rather peculiar that involvement of the third nerve had occurred so late, but he thought this depended on the position of the lesion.

Dr. PARSONS, replying, said that so far as could be seen there was no other lesion of the brain in the second case. His opinion was that these aneurysms were not syphilitic. In his first patient the Wassermann reaction was absolutely negative. In most cases of intracranial haemorrhage it was possible to see patches along the basilar artery.

Reviews.

A TEXTBOOK OF HYGIENE.

THE ever-increasing scope of public health and preventive medicine affords the author of a modern textbook on the subject opportunities that were denied writers of a generation ago. Professor CURRIE of Glasgow University, in his *Textbook of Hygiene*,[1] has made full use of these opportunities, though he has, perhaps wisely, adhered to the more or less traditional arrangement of his subject-matter. The earlier sections deal mainly with hygiene of the environment, then comes an account of public health administration, followed by chapters on such matters as dwellings, food, diseases, vital statistics, and the various social services. The appropriate legal enactments are set out at the end of each section, and English as well as Scottish sanitary law is quoted in sufficient detail. The book is well illustrated, especially that part dealing with meteorology and climatology.

The aim of the author is to present an account of modern hygiene which will meet the requirements of students of medicine studying hygiene and public health under the medical curriculum, and which will at the same time be of service to candidates for a diploma in public health. It is not in any way detracting from the value of the book to say that the medical student will find himself rather out of his depth if he tries to master the bulk of its contents. Indeed, the ideal textbook on hygiene and preventive medicine for medical students has yet to be written. Professor Currie's book is much more suitable for the D.P.H. student, and here it can hold its own with any other published work. Though it is impossible in a single volume to cover the whole field of hygiene, Professor Currie has succeeded admirably in choosing the salient points in each subject for presentation to the student, and, what is more, he has produced a very readable book.

The earlier sections are especially good, that on food being particularly well written. The chapter on statistical methods, although very complete, does not perhaps make sufficiently clear the application of these methods to ordinary public health practice, but the duty of making statistics interesting to the student must obviously lie with the teacher of the subject.

The section on infectious disease opens with a well-balanced summary of present views on infection, immunity, epidemiology and the control of infectious disease, and recent work on such diseases as diphtheria, scarlet fever, and small-pox is fully recorded. Parasitology in its relation to public health is dealt with at some length and in a very clear manner. Maternity and child welfare, school hygiene, industrial hygiene, and port sanitary administration receive adequate treatment, and in the last section of all, headed "Miscellanea," are placed national health insurance, aids to medical practice, health propaganda, and various legal provisions not incorporated in the earlier chapters. The book is remarkably free from error and is well indexed. It is thoroughly to be recommended.

MEDICO-LEGAL ASPECTS OF ACCIDENTS.

IN *Trauma, Disease, Compensation*,[2] Dr. A. J. FRASER, chief medical officer to the Workmen's Compensation Board, Winnipeg, deals with accidents and industrial diseases and their sequelæ in their medico-legal relations. His conclusions are based on experience gained from observing and advising on thousands of cases over a period of twelve years. He makes no claim to originality, professing only to have made a careful collation of these cases and of the opinions expressed about them.

The greater part of the book is given over to a detailed review of the injuries and diseases of the principal systems—the brain and nervous system, the heart and circulatory system, the gastro-intestinal tract, the respiratory system, bones, joints, muscles, etc.—the occupational diseases being

ELECTIVE LOCALIZATION OF STREPTOCOCCI.

LECTURE BY DR. E. C. ROSENOW.

A POST-GRADUATE lecture was delivered on May 26th at the Royal Dental Hospital of London by Dr. E. C. Rosenow of the Mayo Clinic, Rochester, U.S.A., who reported the results of certain experiments which he had undertaken. The devitalized teeth of dogs were inoculated with streptococci derived from various infective lesions elsewhere in the bodies of human patients; similar lesions were reproduced in many of the dogs. The following abstract has been contributed by Dr. Rosenow.

If the streptococci shown to possess elective localizing power on isolation in a considerable number of diseases (as shown in a series of published reports) really have etiological significance in the different diseases studied, then they should localize and produce lesions in the specific organ or tissues, following other methods of inoculation. Owing chiefly to their relatively low virulence, this has been demonstrable in particular instances in different diseases following intraperitoneal, subcutaneous, intratracheal, intratibial, and intraocular infections, and, in diseases of the nervous system, after the intracerebral injection of suitable doses of cultures or of the material obtained directly from foci.

In order to remove all doubt that streptococci showing elective localizing power may produce disease in remote parts of the body through chronic, low-grade, symptomless foci of infection, such as occur commonly in human beings, we have inoculated the teeth of dogs with streptococci shown to possess elective localizing powers. Under ether anaesthesia the four cuspids were isolated, sterilized with tincture of iodine, and severed with a bone-cutting forceps. The pulps were removed and, under sterile conditions, the pulp chambers of three were inoculated with the cultures of the streptococcus in question. The opening was then sealed with gutta-percha and amalgam, and the animals were observed, together with controls, for from two to twenty-four months. Highly specific results were obtained in this series of experiments. Thus of 34 dogs in which the teeth were infected with streptococci from foci of infection and the urine of nine cases of nephrolithiasis, 26 dogs (75 per cent.) developed urinary calculi. Three (60 per cent.) out of 5 dogs inoculated in the teeth with streptococci from two cases of alkaline phosphatic cystitis developed similar calculi. Thirteen (65 per cent.) out of 20 dogs with teeth infected by streptococci from three cases of ulcer of the stomach developed ulcer of the stomach. Seven (47 per cent.) of 15 dogs whose teeth were infected with the diplostreptococcus from chronic ulcerative colitis developed ulcerative colitis. In no instance were lesions other than the specific ones observed in these experiments, but some strains had insufficient infecting power to produce the specific or other disease. Thus, out of 40 dogs whose teeth were inoculated with the streptococcus from sixteen cases of chronic arthritis, not one developed arthritis, nor did any of 38 dogs inoculated in the teeth with twenty-three strains of streptococci from one or more cases of cholecystitis, iritis, chronic encephalitis, spasmodic torticollis, chronic poliomyelitis, goitre, and abortion, develop specific lesions. Five (13 per cent.) showed small calculi in the kidney. Of 1,014 control dogs, the teeth of which were not inoculated, and which were kept and fed in the same way at the institute, 51 (5 per cent.) revealed small urinary calculi, and 6 (0.6 per cent.) ulcer of the stomach.

The relation of the respective streptococcus to the disease produced was substantiated by demonstrating its presence microscopically in the specific lesions and granulomas about the teeth, and by proving that the streptococci isolated from the focus at the apex of the tooth and systemic lesion had, at the end of the experiment, retained specific or elective infecting power. The teeth, rendered pulpless, remained firmly in the jaws; they apparently caused no pain, but became opaque and dark in colour. At the apices, areas of rarefaction were found filled with granulation tissue. The disease produced, especially in chronic ulcerative colitis, ran a typical clinical course, the experimental lesions being essentially like those that occur spontaneously in patients. Sections of the granulomas produced experimentally were often indistinguishable, both as regards the character of the cellular infiltration and the diplococci, from those that develop so commonly about the apices of pulpless teeth in human patients. In the dogs that developed systemic disease, as in patients having chronic disease, the antibody content of the serum was low. The tooth from which the pulp was merely removed often became infected with the streptococcus inoculated into the other three teeth rendered pulpless. The foci produced experimentally with different streptococci, besides giving rise to the specific disease characteristic of the streptococcus inoculated, had other more general deleterious effects. The dogs lost weight and hair, and became highly susceptible to intercurrent infections. A dietary and other living conditions adequate to maintain health in normal control dogs was inadequate for the dogs in which chronic foci were produced experimentally.

In order to throw some light on the mechanism of elective localization, we have injected animals simultaneously with the living cultures, with the corresponding heat-killed bacteria (60° C. for thirty minutes) in larger amount, and with the filtrate of rapidly growing broth cultures. In this way we have found that streptococci having elective localizing power develop in their protoplasm, and set free in the broth, toxins or poisons which injure electively the very tissues in which the living streptococcus becomes localized and produces lesions. This has been shown especially in the case of streptococci from myocarditis, endocarditis, ulcer of the stomach, and epidemic hiccup. An interesting point emerged—namely, that after the living culture had lost the power to localize electively from artificial cultivation or successive animal passage, the dead bacteria and filtrates also no longer had specific effects.

On the basis of our clinical observations and experimental results, a focus of infection which for mechanical reasons cannot heal or drain should be regarded not only as a place affording favourable conditions for entrance into the blood, or lymph stream, of bacteria and their toxic products, but as affording also conditions (relative lack of oxygen, mixture of bacteria) favourable for the bacteria to acquire and maintain peculiar and relatively high infecting power. The focus makes for a forced relationship between living bacteria and the resisting mechanism of the host. Since the bacteria, usually streptococci isolated from foci, have been shown to possess elective localizing power, to contain and produce specific poisons and antigens, and the properties which may render the host and the tissues in which they localize hypersensitve or allergic, the importance of the focus cannot be ignored in any phase of a study of the etiology, pathology, immunology, and treatment of a large number of infective diseases. Since immunity to streptococcal infections is of short duration, the focus will need to be considered even after highly specific curative vaccines and serums are discovered and successfully applied. The importance of high resistance from proper living in the maintenance of continued health is taken for granted.

Devitalization of teeth and the filling of root canals, practised as a routine in the past, at any rate in America, should cease. It is to be hoped that efficient methods will be found that will not only sterilize pulpless teeth and periapical tissues that have become infected, but will also prevent subsequent infection, especially of the periapical tissues. The fulfilment of the latter requirement seems almost unattainable, and until this has been accomplished by the newer methods now being introduced, and which appear more promising, it would seem wiser to remove teeth that have become infected, or that require extirpation of the pulp, than to retain them at the risk of having them become the source of an insidious infection later. Normal vital teeth, free from pyorrhoea, pulp stones, and fillings, should never be extracted, except when necessary for restorative work, but the extraction of pulpless teeth seems to me to be indicated, regardless of the appearance of the *x*-ray photographs. It seems to me also that tonsils should be removed, regardless of whether they are large or small, or whether they are visibly infected or not, unless this is contraindicated for various reasons, in all patients who have serious systemic diseases presumed to be of focal origin, and provided that no other focus can be found. It must not be supposed, however, that other regions, not in any sense foci, may not also harbour the streptococcus with which the disease from which the patient is suffering may be reproduced. We have isolated streptococci in some instances, not only from foci, but also from the more normal mucous membranes of the upper part of the respiratory tract, and from the stools. This may explain why the condition of some patients does not improve following the removal of one focus or more.

It also goes to show that our conception of the principle embodied in focal infection must not be too mechanical. The bacteria that gain entrance through foci must overcome the same inherent resistance of the host as those that gain entrance elsewhere; the factors determining their localization are the same in both instances.

In the demonstrated fact of focal infection and elective localization there is nothing incompatible with the broadest possible concepts regarding the importance of other and more general factors at work in the causation of disease. It does not at all minimize the importance of peculiarities in the host, such as those due to inherited constitutional predispositions, to allergy, to undue fatigue and exposure, to alcoholism, and to intercurrent infections. Indeed, our newer work emphasizes the importance of these, and reveals more clearly how they are operative.

The streptococci isolated are believed to have etiological significance because they have been almost constantly demonstrated in foci and, when available, in the affected tissues. They possess on isolation elective localizing power and the characteristic cataphoretic potentials. The different diseases have been simulated by various methods of injection of freshly isolated strains, and some diseases have been accurately reproduced with the respective streptococci through chronic foci such as occur commonly in human subjects. Most of the strains from the different diseases studied are agglutinated specifically by the respective hyperimmune serums prepared in horses, and which possess curative properties in several of the diseases arising spontaneously in man, as in those experimentally induced in animals with the respective streptococcus.

E. C. ROSENOW.

THE RESEARCH DEFENCE SOCIETY.

ANNUAL MEETING.

LORD LAMINGTON presided at the annual meeting of the Research Defence Society on June 3rd, when the annual report of the committee was presented. The fourth Stephen Paget Memorial Lecture was delivered by Mrs. Mellanby, her subject being the value of animal experiments in determining the question of diet and dental disease.

The committee, whose report was presented by Lord KNUTSFORD, pointed out that the Home Secretary (who was himself on the list of vice-presidents of the British Union for the Abolition of Vivisection) had expressed the opinion that, in view of the thorough investigation by the Royal Commission, which reported in 1912, there was no call at present for further inquiry. This was precisely the attitude taken up by the Research Defence Society, and now that it came from a man who in private life was an antivivisectionist, but who by virtue of his office was in a position to inquire into the true facts, it deserved wide notice. The main trend of antivivisection endeavour during the year had been propaganda against the appeal of the Royal Veterinary College, and against the work of the Medical Research Council. With regard to the former, the society had exposed the absurd position whereby, on the one hand, antivivisectionist societies stood for the prevention and alleviation of animal suffering, while, on the other, they spent their funds on campaigns against the progress of veterinary medicine. As for the Medical Research Council, it was well to remember that, apart from the valuable researches conducted by that body, it had been responsible for some time past for the maintenance, and, in some cases, the development, of the national biological standards for certain drugs and preparations of the utmost value in everyday practice.

Sir LEONARD ROGERS, the honorary treasurer, had no very encouraging report to present. The society had been obliged to realize some of its invested capital in order to meet expenditure; an appeal was made for increased regular annual subscriptions.

Stephen Paget Lecture.

Mrs. MELLANBY'S Stephen Paget Lecture, which was illustrated by lantern slides, recounted her well-known work on the study of the teeth. Mrs. Mellanby confessed that she had started as an antivivisectionist, but, like other antivivisectionists, she knew nothing about the matter except the stories she had heard. At Cambridge, however, she found herself unable to continue her work without taking part in a *vivisection experiment*; she had since seen thousands of so-called *vivisection experiments*, and had come to realize what "a humane crowd of people" were those who were thus engaged. A very large proportion of the total experiments on animals were feeding experiments, though for these, as for others, it was necessary to have a licence, and an inspector was entitled to pay unannounced visits. The work she had to describe, from which results of advantage to children particularly had emerged, entailed the feeding of animals on experimental diets, with the object of ascertaining the effect of variations of feeding upon the structure and arrangement of teeth. She mentioned that the animals were kept in large cages, which were cleaned out every day, and had a bed lined with shavings. In attempting to find out the effect of any one set of conditions animals of the same litter were used, the diets were started at the same time, and the animals killed at the same time. The value of *vitamin D* in the calcification of teeth was illustrated by a photograph of the jaws of four puppies whose permanent teeth were just beginning to develop. The diet of all four consisted of lean meat, separated milk, white flour, a little orange juice, and a little yeast, the only difference being in the type of fat given. The fats were respectively salad oil, butter, egg yolk, and cod-liver oil. With the first of these foodstuffs the structure of the teeth was extremely bad, with the second and third it was good, and with the fourth it was best of all. Vitamin D was absent from salad or linseed oil, and present in abundance in cod-liver oil.

Turning to the structure of human teeth, the lecturer said that it was usually believed that the milk teeth of children were well calcified; but animal experiment had suggested that this could not be widely true, and the result of examining the teeth of a large number of children had convinced her that a very large proportion of children in this country suffered from defective calcification, especially of the milk teeth. In more than 600 cases she found only 1 per cent. in which the milk teeth were nearly perfect, and in 29 per cent. they were very defective. A question arose whether the beginning and spread of decay in human teeth could be influenced by diet *after* the teeth were fully formed. The experiments had shown that after the structure of teeth was established, diet could influence the spread of decay. The proper diet might not be able to arrest decay, though sometimes it did. Mrs. Mellanby also spoke on the presence of pyorrhoea in animals; dogs suffered greatly from this complaint, and the period of early development was of the greatest significance from the point of view of subsequent pyorrhoea. In conclusion, Mrs. Mellanby said that in the work she had described, experiments on animals had been the means of leading to a better understanding of the facts of human dentition. Experiments on animals and investigations on human beings had been intermingled in this research, but, of course, it had to be remembered that only beneficial influences could be tested on man. The worst errors in feeding, especially of children, were now known, and permanent improvement only became possible as a result of animal experiment, which could never have been undertaken if a small section of the community had had its way.

At the conclusion of the lecture a lady in the audience desired to put some questions to Mrs. Mellanby, but these were disallowed by the chairman as irrelevant. The proceedings closed with a vote of thanks to the lecturer, proposed by Lord KNUTSFORD, who commented upon her combination of expert knowledge and disarming modesty.

THE annual meeting of the American Medical Association will be held this year at Detroit from June 23rd to 27th, under the presidency of Dr. William Gerry Morgan of Washington. The scientific proceedings have been organized in fifteen sections. A special feature of this meeting will be the presentation of symbolic medals to ex-presidents of the Association. All the eighteen past-presidents now living, except Dr. W. W. Keen who is 93 years of age, will attend in person to receive the emblem. A portrait of each appears in the special Detroit number of the *Journal of the American Medical Association* dated May 24th.

British Medical Journal.

SATURDAY, JUNE 14TH, 1930.

DISSEMINATED SCLEROSIS.

By common agreement disseminated sclerosis is at the same time one of the most common and one of the most intractable organic diseases of the nervous system. None of the various theories of its etiology hitherto advanced have met with general acceptance. Hence the claims recently put forward by Miss Kathleen Chevassut[1] to have isolated the causal organism have naturally aroused the greatest interest, although it is desirable to await the confirmation of other workers before these claims can be definitely accepted. Dr. Russell Brain's[2] critical review of the whole subject of disseminated sclerosis appears, therefore, at a particularly opportune moment. Any student of the disease should be much indebted to him for the careful manner in which he has sifted the now enormous literature and provided the reader with a condensed but highly pertinent résumé, not only of the pathogenesis, but of every aspect of the disease.

Modern histological methods have definitely placed disseminated sclerosis as an inflammatory affection of the central nervous system, of which the sclerotic plaque is but the end-result. In their distribution the inflammatory patches tend to occur principally in three situations: (1) perivascular, (2) subpial, (3) periventricular; the absence of any marked secondary degeneration of nerve fibres is a characteristic feature which has long been recognized. There is no general agreement as to whether these changes are produced by a toxin acting through the blood stream or by some definitely neurotropic infective agent; but at the present time a preponderance of opinion inclines towards the latter view, which is certainly supported by comparison with other forms of encephalomyelitis in which very similar pathological changes occur. Dr. Brain considers that there is evidence that both the blood stream and the cerebro-spinal fluid may play a part in the spread of the infection.

Positive knowledge of the nature of the infecting agent is still absent until the recent claims of Miss Chevassut have been confirmed. The spirochaetal theory of the disease, first promulgated by Bullock in 1913 and later supported by Kuhn and Steiner and by Adams and others, has failed to receive general acceptance. Moreover, the numerous experimental attempts to transmit the disease do not carry conviction. Miss Chevassut has put forward strong claims to have isolated from the cerebro-spinal fluid of cases of disseminated sclerosis an organism which has been named the *Spherula insularis*, but the attempts made at transmitting the affection to animals cannot be said to have reproduced anything really resembling the disease in man. It is highly desirable that her work should be repeated by others, but in view of the difficult nature of the technique some time must elapse before any definite conclusions can be established. A line of treatment based upon the discovery of Miss Chevassut has been suggested and practised by Sir James Purves-Stewart,[3] consisting in the intravenous injection of a vaccine made from cultures of the *Spherula insularis*. In view of the well-known tendency for cases of disseminated sclerosis, especially of the more acute forms, to display spontaneous remissions, which sometimes indeed amount to a complete disappearance of all the symptoms, it is certainly premature to draw any definite conclusions as to the value of such a method of treatment. Dr. Brain refers briefly to most of the therapeutic measures which have hitherto been employed, and remarks, justly enough, that their large number is sufficient evidence of their inadequacy. Many observers, however, do attach a definite value to the use of arsenic, especially in the form of one of the salvarsan compounds.

It is of much practical as well as academic interest to consider the possible relationship of disseminated sclerosis to other disseminated inflammations of the central nervous system. This problem is briefly reviewed by Dr. Russell Brain, who points out how difficult it is to separate clearly such conditions as the so-called neuromyelitis optica and acute disseminated encephalomyelitis from acute cases of disseminated sclerosis. Many authorities, indeed, are not prepared to distinguish them. It is greatly to be hoped that the work of Miss Chevassut, even if it should fail of confirmation by others, will provide an impetus to a renewed investigation into all the problems of this disease, not only in this, but in other countries.

PHYSIOLOGY AND PUBLIC HEALTH.

SEVERAL important questions at once arise when it is asked how best can increased emphasis be laid on the preventive aspects of medicine in the training of medical students and at the final test of their fitness to be registered as medical practitioners. In the first place it may be contended that these aspects, even more fully than the curative or clinical aspects, are dependent upon a knowledge of the preliminary sciences of physics, chemistry, and biology, and of the pre-clinical subjects of human anatomy and physiology. The information, therefore, which the General Medical Council has recently been obtaining about the manner in which the teaching of all these pre-clinical subjects is continued during the later student years, and the inquiry into the best methods of correlating these sciences with the needs of actual medical practice, is of importance quite as much in respect of prevention as in respect of clinical and curative work. The final examination of a student is not to be regarded merely as a more or less satisfactory test of attainment; it is an encouragement to the continuance of effective study in all those subjects with which it is liable to deal. It is found that, except in applied anatomy, definite questions on the pre-clinical subjects are seldom set in the final examination papers. Would it not have an equally good effect if it were understood that a question on applied physiology must be answered in the final paper on medicine; and that in the clinical examination the candidate might have to report on the condition of a healthy subject and his suitability for work of various kinds, and not merely to diagnose some condition of disease?

A second fundamental question is whether or not it is desirable to associate the teaching of the preventive aspects of medicine, and the testing of the results of such teaching, with lectures and examinations dealing specifically with what is known as "public health." In a recent report on "Preventive Medicine in the Curriculum" (*Journal*, May 24th, 1930, p. 968) the Society of Medical Officers of Health recommends that each student should be compelled to attend a "special

course on public health and preventive medicine," and should have to pass a "separate examination in public health and preventive medicine." It may well be held that this is an unfortunate way of presenting a good case. There is much force in the contention that all students should attend lectures and receive other instruction in matters of public health, including the duties of private practitioners in relation thereto, and should be examined as to their knowledge of these matters; but it would be lamentable to do anything which would tend to identify the practice of preventive medicine with the organized public health service. The preventive aspects of medicine extend much more widely than this, and from the beginning they should be regarded and taught as an intimate part of the work of every practitioner, inseparable from his clinical activity and duty.

A third question that has recently been raised is whether members of the public health medical service are really on the right lines in some of the later developments of their work. This has been forcibly put by Dr. G. C. M. M'Gonigle, the medical officer of health for Stockton-on-Tees, in his presidential address to the Northern Branch of the Society of Medical Officers of Health, published in the May number of *Public Health*. His address is well worthy of notice and discussion by his colleagues in the public health service and in the profession outside. That service has been notably successful in dealing with environmental factors that are detrimental to health. Beyond this, Dr. M'Gonigle says, it is the duty of the service "to maintain normality and not to undertake curative medical practice, though of late much curative work has been thrust upon us." He contends that the study of physiology—he calls it "normal biology"—should be the foundation of the business of the "practitioners of preventive medicine," and that that business is "to teach correct living and not to remedy defects." While acknowledging the good work that has been done, he gives a number of striking instances, and asks a number of pertinent questions, which tend to raise grave doubts as to the validity of certain common hygienic dicta, and as to whether all the present work of public health clinics is on safe lines. The application of physiological truths to the art of living, and especially to the rearing of children, should certainly now become one of the main functions of "practitioners of preventive medicine."

THE B.C.G. DISASTER AT LÜBECK

REPORTS from Berlin on June 6th stated that of the 246 children in Lübeck to whom B.C.G. vaccine had been administered during March and April, 28 were dead, 103 were still ill, and 86 had been ill but had fully recovered. It will be recalled that the authorities at Lübeck were of the opinion that no contamination of the cultures could have occurred during their transit from Paris, or in the course of their further development in Lübeck itself. None the less, a number of separate investigations were started with a view to discovering if careless or negligent handling of the cultures, or their pollution, could be held responsible for the infections. In view of Petroff's work on the virulence of B.C.G., in the course of which he claims to have cultivated from this preparation two separate colonies, "R" and "S," of which the latter is capable of producing progressive tuberculosis, it was necessary also to consider the possibility that in the course of cultivation the "R" colonies had reverted to the "S" type, and so had increased the virulence of the vaccine. Professor Bruno Lange, of the Robert Koch Institute, Berlin, who has been in charge of the investigations on behalf of the State Office of Health, rejects completely any explanation based on Petroff's findings. According to Lange[1] an examination at the Robert Koch Institute of colonies cultivated by Petroff showed that they contained human tubercle bacilli, obviously a contamination, as transmutation of bovine organisms—from which B.C.G. is cultivated exclusively—to organisms of the human type has never been shown to occur. Petroff, in replying to Calmette and his colleagues, who had dismissed his work on similar grounds, said that it was no justifiable criticism to accuse him and his research associates, all trained workers, of such gross carelessness.[2] The outcome of Lange's report is that, while he is convinced that the fatalities among the inoculated infants were due to the presence in the vaccine of virulent tubercle bacilli, he can hold out very little hope of discovering how they found their way there. Investigations, he states, will continue for several weeks; but, unfortunately, neither the original material from the Pasteur Institute nor the first subculture is available for study. Meanwhile, according to reports from Berlin, the citizens of Lübeck have set up their committee of inquiry, and an inquiry is also being made by the department of the public prosecutor.

HYGIENE AT THE JAMBOREE CAMP.

DR. R. WYSE, who was chairman of the hygiene subcommittee which controlled the sanitary arrangements in connexion with the Jamboree camp of over 4,000 boy scouts last August at Arrowe Park, Birkenhead, has compiled a full account of the measures which were taken. In a previous reference (*Journal*, August 10th, 1929, p. 275) mention was made of certain outstanding points, and of the success achieved in the preservation of health. The committee, when it came into being, found itself unable to obtain any detailed guidance from existing literature for safeguarding the health of a camp of this kind, and it is therefore most desirable that the experience gained on this occasion should be made available for others who may have similar responsibilities to face in the future as regards latrine construction; the supply of water; the disposal of refuse; the campaign against flies, mosquitos, and gnats; and the prevention of infectious diseases. Dr. Wyse, in his preface, dwells on the importance of forming a committee composed of medical officers of health, medical practitioners with public health qualifications, sanitary inspectors, and experienced Territorial officers; he remarks that in this way the work is made very easy, as well as very pleasant. Details are given of the planning and construction of the latrines and their cleansing; here, as elsewhere in his booklet, Dr. Wyse discusses the various possibilities, indicating their relative advantages and disadvantages, and stating in each case why each particular decision was made. Numerous pictorial illustrations are provided, and a pleasing feature of the whole booklet is the repeated occurrence of definite suggestions—for example, how the necessary agreements should be drawn up with contractors, the chief requirements being enumerated. As regards the water supply, arrangements had to be made for some 50,000 persons, and the estimated rate for each was three gallons per day. The quantity used was two and a half gallons a head per diem, and, since the usual daily domestic consumption is estimated at twenty-five gallons, an indication is given how economical in this respect camp life actually is. The supply was so arranged that no scout had to walk more than 100 yards to obtain drinking and cooking water, but he might have to travel further for washing purposes. Pipes were laid along the ground for the most part; only half a mile of the total five and a half miles of piping had to be dug in. Standpipes were placed at intervals, and

[1] *Deut. med. Woch.*, May 30th, 1930, p. 927.
[2] Forty-fourth Annual Medical Report of the Trudeau Sanatorium.

each of the ninety-eight required was supplied with six half-inch taps at a height of three feet from the ground, the whole structure being protected by wooden supports. Ordinary screw taps were employed, and water wastage was controlled quite easily by camp discipline. One pathetic note is sounded in this connexion. A week before the camp opened arrangements were made by the Water Board to irrigate the rally ground in order to stimulate the poor growth of grass following the spell of dry weather. No sooner had this been done, however, than what Dr. Wyse mildly describes as "phenomenal" rain fell almost continuously for a week. Refuse was removed in motor wagons by the sanitary department of the Birkenhead Corporation, and there was not a single incinerator in the camp. The quantity dealt with amounted to twenty tons a day, and an interesting comparison is made by Dr. Wyse showing what would have happened had any other method of destruction been adopted. A list of practical suggestions for future camps, whether of boys or men, contains hints that it is well to have the bins for waste food coloured differently from those for rubbish, and that the contractors should be instructed to make their rounds in the same order each day. Before the camp opened the Birkenhead scouts had thoroughly disinfected every pond and streamlet on the estate, and, whether for this reason, or owing to the climatic conditions, no insects invaded the camp; it was observed, moreover, that in private houses in Birkenhead, during the remainder of the summer and autumn, there was a very remarkable absence of flies. Details are given of the measures taken to prevent the outbreak of infectious diseases; the success attained in this respect is a matter of common knowledge. Dr. Wyse is to be congratulated on the production of a valuable handbook. It is published by Messrs. B. Haram and Co., Ltd., Printers, Birkenhead, and the price is 2s. 6d.

ATMOSPHERIC CONDITIONS IN TEXTILE MILLS.

THOUGH New South Wales is not by any means to be considered as an industrial State, there is attached to the department of the Director-General of Health a special section of industrial hygiene. It is in the charge of Dr. Charles Badham, who, with his several technical assistants, has already proved what useful research work can be carried out in connexion with occupations which, though not necessarily industrial, are of some importance in Australia. Since 1923 fifteen reports have been published dealing with such subjects as sandstone quarrying and working, silicosis, dermatitis among rubber workers, lead poisoning, and textile factory conditions. The practical outcome of these investigations has usually been an issue of, or alteration to, regulations. The latest report of the series was officially published, under the heading "How to improve atmospheric conditions in textile mills,"[1] at the end of 1928, but has only just reached this country. Temperature and humidity have hitherto been dealt with by general factory regulations, but as spinning and weaving of wool and cotton are increasing it was considered necessary to make thorough investigation into the relationship of these atmospheric conditions to textile processes, the result being that it is deemed advisable to vary the regulations in their application to textile industries. We have knowledge of a cotton factory in Sydney, and there may be others elsewhere, but the investigators apparently limited their efforts to wool-spinning mills, so that the report may be taken as applying to this branch of the textile industries. In this country and in India a great deal of research work on atmospheric conditions has been carried out during recent years, but mainly in relation to the cotton industry and, in lesser degree, to the linen industry. The value of this work, and its bearing on their own problems, is suitably acknowledged, and Dearden, Hill, Maloney, Vernon, and Wyatt are extensively quoted. The climate of Sydney is equable and considered fairly suitable for wool spinning, its summer temperature being about equal to that of an Indian winter, and its annual range of humidity being between 60 and 80 per cent. Processes are divided into two classes: the first, which takes in frame-spinning, covers those requiring a humidity not greater than 55 per cent. at 75° D.B., and the second a humidity above this at the same temperature, which mainly applies to mule-spinning. Natural ventilation methods are suitable for frame-spinning during most of the year, but dry westerly winds necessitate the use of sprays, and cold weather requires artificial heating and sometimes artificial humidity. Mule-spinning requires artificial humidity for practically the whole year, and to supply this the plenum system, with additional sprays for use when needed, is approved. It is claimed that the basic metabolism of the Australian operative is lower than that of the British operative, and that he can therefore tolerate a higher wet bulb temperature. Provided, then, that the workers are suitably clothed and air movement is sufficient, it is suggested that 85° W.B. should be the "cease work limit," instead of 80° W.B. as in British weaving sheds. Air movement is insisted upon in both classes when the temperature exceeds 80° D.B., and a wet kata standard of 14 is recommended. It is advised that plans for new buildings should be approved by the factory department and that no young persons under 16 years should work at a Class II process. The report is well worth the attention of our own Factory Department, which does not appear to have done very much towards improving atmospheric conditions for cotton and wool spinners.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

THE sixteenth annual conference of the National Association for the Prevention of Tuberculosis will be held in the Great Hall of the British Medical Association House, Tavistock Square, from July 3rd to 5th. The Minister of Health will open the conference at 10.30 a.m. on the first day, and introductory addresses will be delivered by Sir George Newman and Dr. J. Parlane Kinloch. The main subject for discussion is the effects on the tuberculosis campaign of the Local Government Act, 1929, and the first part—which will follow the introductory addresses—will be devoted to the effect on the institutional treatment of tuberculosis. In the afternoon of the first day consideration will be given to the relation of the general practitioner to the treatment of tuberculosis, with special reference to domiciliary attendance; this will be followed by a discussion on tuberculosis in relation to education, including the work of open-air schools, nursery schools, and the feeding of school children. The conference will be opened on the second day, July 4th, by Dr. Walter Elliot, M.P., late Parliamentary Under-Secretary of State for Scotland. The subjects at the morning session will be: tuberculosis and factory workers; the change from the percentage grant to the block grant as affecting the efficient development of tuberculosis schemes; and the way in which the Act affects the problem of continuous care in tuberculosis. The afternoon session will be devoted to social aspects of the problem, with special reference to care committees, district nurses, health visitors, and other health agencies. Interesting excursions are being arranged for the third day, details of which will be sent later to all delegates. The conference is open to all persons interested in tuberculosis, on payment of a fee of one guinea, which includes the cost of a copy of the report of the proceedings. Reduced railway fares will be available, and payment of the expenses of delegates has been sanctioned by the Ministry of Health and the Department of Health for Scotland. Further information

may be obtained from the secretary of the National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock Square, W.C.1.

THE UNMARRIED MOTHER AND HER CHILD.

THE eleventh annual report of the National Council for the Unmarried Mother and her Child is chiefly concerned with the efforts of that body to obtain reform of the existing *Bastardy Acts* and *Affiliation Acts*, so as to ensure that fathers who emigrate to escape their responsibilities may be compelled, by reciprocal legislation, to fulfil their duties to their illegitimate offspring. At present an affiliation summons issued in England against the father of an illegitimate child cannot be served even in Scotland or Ireland. The influx to England of unmarried Irish mothers is said to be creating a serious problem. The council has also paid attention during 1929 to the obscurities of the Legitimacy Act (1926) and to the safeguarding of the Act of Adoption. It regards with some apprehension the coming operation of that part of the Local Government Act which places all local and voluntary homes under county councils or county borough councils, for, if a local authority controls the grant, it may refuse applications from those residing in another area. On the other hand, the expectant mother is usually eager to leave her own neighbourhood, and would be so reluctant to permit any kind of inquiry in her home district that she would probably refuse the assistance of a maternity home altogether, with subsequent danger to her life. Assurances of discretion and suggestions of reciprocity between the areas have been received by the council. Figures are quoted to prove that the maternal death rate is highest among unmarried mothers. The hope is expressed that the inquiries conducted by the Maternal Mortality Committee of the Ministry of Health will lead to the frequent publication of comparative statistics. One reason for the preponderance of deaths among unmarried mothers is believed to be the sale of abortifacients by unscrupulous vendors. The Case Committee has found evidence that drugs dangerous to health or life are recommended and sold over the counter, and that there exists a system of fraud in the sale of pills and powders purporting to be "a certain cure." The report has much value as evidence of a growing body of opinion that the unborn child *demands* rather than pleads from the community the best chance of health possible, and that *anything* so vulnerable cannot be left to bear the burden of the follies or misfortunes of its parents.

THE OUTBREAK OF TRICHINOSIS IN STUTTGART.

BRIEF accounts by Dr. K. Beckmann and Dr. Weitz of an outbreak of trichinosis at Stuttgart were published in the *Medizinische Welt* of April 26th; the reports are only preliminary, since many cases are still in the pyrexial stage. It appears that from February 15th to March 4th bear ham was on sale in a restaurant; it came from a polar bear, shot because it was becoming blind. Other of the bear meat was sold also, but as that was well cooked no disease resulted. The microscopical examination of most meats has been required for three years at Stuttgart, but, unluckily, bear meat had not yet been scheduled. So far seventy-five cases of trichinosis have been seen, with already ten deaths. One man ate only the well-smoked edges of the bear ham, and he escaped illness. The encysted trichinae are liberated in the small intestine, where they rapidly become sexually mature and conjugate; in about three days the fertilized females pass through the intestinal walls into the lymph spaces, whence their numerous offspring, in successive broods, make their way into the circulation by way of the thoracic duct. They thus reach the voluntary muscles when they leave the circulation, and become encysted in two or three months. The first symptom is diarrhœa, usually slight, with offensive stools and nausea. At this stage there is a slight pyrexia which tends to subside; there is no eosinophilia yet. In the next week the temperature rises again, the pulse is accelerated, and the patient is weak, the condition suggesting typhoid fever, but a leucocytosis is present with notable eosinophilia. The weakness of the patient soon attracts remark, and he cannot walk or even stand. Kernig's sign is positive, but there is no patellar tendon reflex because the contracting muscles are so painful. Pyrexia increases, and in one case the temperature reached 106.5°; the pulse may be as rapid as 140. The muscles are tender to pressure and the skin overlying them is swollen. The blood pressure is low, sometimes dangerously low. Pain may be obvious in the muscles of the jaws, larynx, pharynx, arms, and legs. The patient may be unable to protrude his tongue, which may be fissured, swollen, and furred. Respiration may become thoracic owing to involvement of the diaphragm, while sweating and sleeplessness cause serious discomfort. Widal's reaction is negative, the diazo-reaction positive, and the spleen is sometimes enlarged; albuminuria does not occur. The blood picture, unchanged at first, soon shows a leucocytosis of 10,000 to 14,000, and even 22,400, with eosinophilia to 40 per cent.; in four fatal cases reported the eosinophilia was only 8 to 12 per cent. At the necropsy cysts are found of varying age, showing that there have been successive broods. The treatment is symptomatic, calomel and vermifuges being prescribed in the first week; but few patients complain to a doctor so early as this. Later on the pain and sleeplessness have to be relieved, a watch being kept on the heart and lungs. The patients are very weak, and convalescence is protracted. Perusal of these reports recalls the completeness of Osler's classical account of this disease thirty years ago.

BROADCAST EPIDEMIOLOGICAL INTELLIGENCE.

THE Singapore Bureau of the Health Organization of the League of Nations has for some years been doing valuable work in preventing the spread of disease by acting as a collecting and distributing centre of epidemiological intelligence in the Far East. The value of this information service will be increased by a recent development which should be of considerable interest to shipping companies with business in the East. A broadcast summary in clear of infectious diseases and quarantine notifications is now sent out daily—instead of weekly, as hitherto—from the long-range station at Malabar (Java), and the wireless stations at Hong-Kong (Cape d'Aguilar), Karachi, Madras, Sandakan (British North Borneo), Shanghai (Zikawei), and Tokyo also broadcast weekly epidemiological information in clear for the benefit of ships in Eastern waters. Reports received at Singapore from captains as a result of these messages show that on the whole run from Suez to Japan it is possible for ships to pick up one or more of these stations; Malabar, owing to its range and daily transmissions, being the one most frequently quoted. The broadcast summary is based on information on their bill of health and related subjects received from more than 140 ports and broadcast in code to over thirty health administrations. Owing to lack of wireless facilities in Singapore it is practically impossible for the Eastern Bureau to check the working of its radio services; it would therefore welcome further reports from captains of ships as to their success or failure in picking up these health bulletins, as well as any suggestions which may help to increase the efficiency of this information service. Such reports should be addressed to the Director, Eastern Bureau, League of Nations, Singapore.

Orthopaedic treatment was given to children under the age of 5, a clinic being held as often as was found to be necessary. At the end of 1928 five cases of mild small-pox remained in the Pontypridd and Caerphilly joint small-pox hospital; 35 further cases were notified during the early part of 1929, several of the patients being seriously ill. No "return" cases occurred as the result of the discharge of patients from hospital. The local medical practitioners co-operated intimately with the medical staff of the health department, consulting them in difficult cases; contacts were closely followed up, and doubtful diagnoses of chicken-pox were confirmed. As a result of these energetic measures an epidemic of small-pox which had persisted for more than two years was brought to an end. There was a falling off in the total of public vaccinations for 1929, as compared with 1928, in consequence of the regained feeling of security on the part of the inhabitants. The report contains details of the scheme for the provision of meals to undernourished school children, which was first commenced in October, 1928. A complete survey of the whole school population was made in October, 1929, by the assistant school medical officer, and the influence of the greater prevalence of unemployment was shown by the considerable increase in the number of children receiving free meals. It was, however, found impracticable to issue milk to children prevented by illness from attending school. A special clinic is held each Saturday for the medical inspection of children suspected to be subnormal, many of them being referred by the head teachers, who are in a position to know the home circumstances of the cases. If evidence of malnutrition is discovered by the medical officer, milk is prescribed. Dr. Severn has no doubt that the application of this scheme has been of inestimable value in combating the evil effects on young children of parental unemployment; its completeness has allowed little loophole for any needy children to remain hungry in school.

Training in Social Hygiene.

The growth of the child guidance movement has created a demand for a new type of social worker trained in normal and abnormal psychology, and in the practical application of the principles of mental hygiene in the treatment of maladapted children. Such social workers are needed not only by child guidance clinics, but by mental hospitals, associations for the care of mental defectives, and similar agencies, for it is now realized that the adequately trained lay worker can play an important part in helping persons suffering from psychological illness, or handicapped by temperamental difficulties, to take their place in the life of the community. Hitherto there have been no special courses of training in this country for men and women wishing to undertake this difficult and responsible task, but, beginning in October, a special one-year post-graduate course, covering the appropriate subjects, will be held in the Department of Social Science and Administration of the London School of Economics and Political Science. The course will be repeated each year. The theoretical sides of the subject will be dealt with in lectures on psychiatry, psychology, and social case work, special stress being laid on the psychological development of the child, the characteristics of different stages of mental abnormality, the psychological foundations of abnormal behaviour, the formation of personality, the bearing of psychiatry on family relationships, and the methods of studying the individual mind. The practical work will include visits to the homes of children and adults who are under treatment at child guidance or hospital clinics, inspection of institutions and hospitals, and case discussions, conferences, and demonstrations. Students will be admitted to the course on the recommendation of a selection committee, and, generally speaking, they will be accepted only if they are over 25 years of age, have already obtained a social science certificate at a university, and have had experience of some form of social work. The fee for the course is thirty guineas. The Child Guidance Council offers six scholarships of £181 10s. each to students desiring to take the course. Application forms may be obtained from Miss E. V. Eckhard, London School of Economics, Houghton Street, W.C.2.

Ireland.

Royal College of Surgeons in Ireland.

THE annual election of officers of the Royal College of Surgeons in Ireland was held in Dublin on May 2nd, when Mr. Richard Atkinson Stoney was elected president, Mr. Frank Chetwode Crawley vice-president, and Sir F. Conway Dwyer secretary of the College. The newly elected president has taken a keen interest in the College, where he has served as an examiner, member of council, and vice-president. He comes as a successor of men whose names are household words in the medical world, such as Crampton, Carmichael, Abraham Colles, Butcher, Jolliffe Tufnell, Sir Philip Crampton Smyly, Edward Hallaran Bennett, Sir Charles Cameron, and Sir Henry R. Swanzy. He is surgeon to the Royal City of Dublin Hospital, surgeon specialist to the Ministry of Pensions, and honorary surgeon to the Masonic Boys' School. During the war he served as surgical specialist in the French army, and was created a Chevalier of the Legion of Honour. He has written many interesting papers on surgical subjects. Mr. Frank Chetwode Crawley, the new vice-president, is a graduate in arts of Cambridge University and in arts and medicine of Dublin University, having taken his medical degrees in 1896. He has been a Fellow of the Royal College of Surgeons in Ireland since 1900, and is ophthalmic surgeon to the Royal City of Dublin Hospital, surgeon to the Royal Victoria Eye and Ear Hospital, Dublin, consulting ophthalmic surgeon to the Rotunda Hospital, a Fellow of the Royal Academy of Medicine of Ireland, and president of the Ophthalmological Society of Great Britain and Ireland. Mr. Crawley acted as examiner in ophthalmology for many years, and during the war served with the Dublin 83rd General Hospital in France. Mr. Crawley's many friends "on the Island" will appreciate the honour he has received.

Vital Statistics for Northern Ireland.

During the quarter ended March 31st, 1930, 6,359 births were registered in the twenty-seven superintendent registrars' districts in Northern Ireland, this number representing an annual birth rate of 20.4 per 1,000 of the estimated population. The equivalent figure for England and Wales is 16.2, and for Scotland 19.7; the rate in Northern Ireland is 0.2 above the rate for the corresponding quarter of 1929 and 2.4 below the average rate for the first quarters of the ten years 1920 to 1929. Deaths registered during the quarter numbered 5,265, or an annual rate of 16.9 per 1,000. This rate is 7.8 below the rate for the corresponding quarter of 1929, and 2.2 below the average rate for the first quarters of the ten years 1920 to 1929. The urban mortality from the principal epidemic diseases recorded during the quarter was equivalent to an annual rate of 0.7 per 1,000 of the population, the death rate from these diseases being 0.4 for the remainder of Northern Ireland. Deaths from cancer numbered 392, being equivalent to an annual rate of 1.26 per 1,000, as compared with an average of 1.12 for the previous five years. The number of deaths of infants under 1 year of age was equal to 78.2 per 1,000 births registered.

School Inspection in County Derry.

Dr. Matilda Watson, school medical officer for the Derry and Limavady area, in the course of her annual report for 1929–30, states that the number of children who presented themselves for examination was much the same as last year—namely, 73 per cent. of those on the rolls. A larger proportion than previously was examined in the Limavady schools, and many who had refused examination last year had come forward willingly. Dental caries was still the most common defect; this had increased during the year from 36 per cent. to 42 per cent. Since the school inspections were completed much progress had been made in dealing with this defect under the free dental scheme. The number of children suffering from enlarged tonsils and adenoids was still very large—namely, 22 per cent., com-

pared with 26 per cent. last year. A considerable number in the Dungiven district, mainly private patients, had their tonsils removed. It was found that 330 children, representing 9 per cent., suffered from defective vision. Some of these cases were very slight; others irremediable. Twenty-eight children suffered from defective speech, but they were all able to learn at school in spite of this disability. There was a definite improvement in some of the younger children who had been defective last year. Only 29 children were anaemic, compared with 57 in the previous year. In several cases the school teachers provided suitable medicine and administered it personally after having obtained the parents' permission. Next year the cases of anaemia should be still further reduced. The commonest nervous disease was epilepsy. Two children who had chorea were advised long rest from school work and referred to their own doctors for treatment. The nurses who had followed up these cases reported improvement.

Typhus in County Mayo.

Following an outbreak of typhus fever in the Cashel district of County Mayo, eleven patients affected with the disease were admitted to the Swinford Fever Hospital. A wardsman in the hospital who assisted in the removal of some of the patients contracted the disease, and one death is reported. The cases are all confined to the Foxford dispensary district. When the matter was reported to the Department of Local Government and Public Health a medical inspector visited the district. On inquiry at the Department of Local Government and Public Health a press representative was informed that the situation was well in hand, and that everything was being done to prevent a spread of the disease. Dr. Stephenson, Chief Medical Officer of the Department of Local Government and Public Health, stated that all the patients were now in hospital, and he did not expect any further outbreak. The houses in which the disease occurred have been thoroughly disinfected, and the entire locality is under medical observation.

A Medical Officer's Salary.

At the last meeting of the County Wexford Health Board a letter from the Department of Local Government and Public Health, refusing to sanction a salary of £100 per annum for the medical officer of the county fever and auxiliary hospitals at New Ross, was under consideration. The Department in its letter stated that the salary offered was totally inadequate. After discussion, the salary was fixed at £200 a year.

Scotland.

Health of Scotland.

THE return of the Registrar-General for Scotland for the quarter ending March 31st, 1930, records that the birth rate was 1.9 per 1,000 higher than that of the previous quarter, and 0.3 higher than that of the first quarter of last year, although it is still 3.3 lower than the mean for the first quarters of the preceding ten years. The death rate for the quarter—namely, 15.8 per 1,000—was 3.4 higher than that of the previous quarter, but 6.1 lower than that of the first quarter of last year, when influenza was prevalent in the country. The death rates per 100,000 from all forms of tuberculosis and from tuberculosis of the respiratory system were 96 and 67 respectively, both of these being higher than those of the previous quarter, although lower than those for the first quarter of last year. Deaths from malignant disease numbered 1,750, representing a death rate of 145 per 100,000. The number of deaths from this cause was 63 less than in the previous quarter, but 18 more than in the first quarter of the past year. Deaths from diseases and accidents of pregnancy and childbirth numbered 194, which represents a mortality rate of 8.2 per 1,000 births, this number being 64 more than that of the previous quarter. Deaths from violent causes numbered 804, an increase of 42 over that of the previous quarter and 53 over that of the first quarter of last year. Of these, 152 were attributed to motor accidents—23 more than in the first quarter of the preceding year. The deaths of children under 1 year of age numbered 2,593, representing an infantile mortality rate of 110 per 1,000 registered births. This figure was 415 less than in the first quarter of the previous year, and the same as the mean of the first quarters of the preceding five years. The six principal epidemic diseases accounted for 866 deaths, or 4.5 per cent. of all deaths, the chief causes of mortality being measles and whooping-cough, which were responsible for 355 and 178 deaths respectively. The death rate from this cause was 0.7 per 1,000, the same as that of the first quarter of the preceding year. The number of deaths from cerebro-spinal meningitis was 63, and from encephalitis lethargica 36, which was respectively 23 and 12 more than in the previous quarter.

Memorial to Dr. Dawson Turner.

A memorial tablet, erected in the radiological department of the Royal Infirmary of Edinburgh to the memory of Dr. Dawson Turner, for many years radiologist to that institution, was displayed on June 3rd to the friends and co-workers who were responsible for its erection. The tablet is the work of Mr. C. d'O. Pilkington Jackson, and consists of a marble panel with the Turner coat of arms and the following inscription: "In Memory of Dawson F. D. Turner, M.D., F.R.C.P.E., F.R.S.E., Pioneer and founder of Roentgen Ray and Radium Work in the Royal Infirmary, Edinburgh. 1899–1925. Prosper Thou the work of our hands upon us, O prosper Thou our handiwork."

Morison Lectures at Edinburgh.

The annual Morison Lectures of the Royal College of Physicians at Edinburgh were delivered on June 2nd, 3rd, and 4th by Dr. S. A. Kinnier Wilson of London, who took as his subject nervous semeiology. In the first lecture Dr. Wilson dealt with the relation of nervous symptoms to nervous lesions, explaining the physiological nature of symptoms and dwelling upon the defects of the clinical-anatomical method. In the second lecture he discussed the symptoms indicative of release or increase of neural function, and considered the auras, fugues, and other symptoms associated with the highest level type of fits, as well as the reflex epilepsy associated with middle level fits. In the third lecture he continued to discuss the symptoms associated with release of neural function, and dealt with fits of infracortical origin, such as striatal epilepsy, tonic cerebellar fits, and periventricular epilepsy.

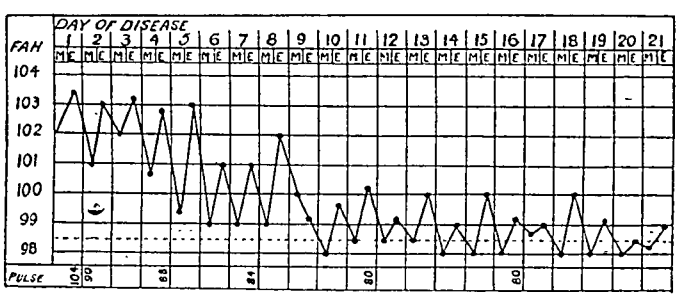
Small-pox in Aberdeen.

A single case of small-pox has been notified in Aberdeen, the case being that of a woman aged 30. As the patient was employed in the handling of material imported from abroad, it is thought that the fomites have been responsible for carrying the infection, and arrangements have been made for the vaccination of all those engaged in the same employment. Arrangements have also been made for the free vaccination or re-vaccination of any who care to submit themselves.

Home Relief for Incurables.

At the annual meeting of the Royal Society for Home Relief to Incurables, Lord Provost Whitson, who presided, said that the society had been in existence for 125 years. During the past year £4,900 had been distributed among the beneficiaries in all parts of Scotland. Dr. J. Haig Ferguson, President of the Royal College of Surgeons, said that short of the prevention or abolition of disease there could be no nobler function than to promote the comfort and mitigate the anxiety of those who were permanently disabled. He hoped that within the next fifty years the victory which had been achieved over tuberculosis would be achieved in the case of cancer. As a number of people would always be permanently incapacitated he thought that there would always be scope for the work of the society.

Correspondence.



GLANDULAR FEVER WITH ROSEOLAR RASH.

SIR,—Is it not probable that there is a definite connexion between the obscure exanthem referred to by Drs. Cantor and Shulman (*Journal*, May 24th, p. 976) and the outbreak of glandular fever reported by Drs. Letheby Tidy and David Krestin in your issues of May 10th and 24th? Such a connexion is suggested to me by a case at present under my care, which combines the distinctive fevers of each in striking fashion.

The patient, a young City man aged 26, was taken ill on May 15th with exactly the same train of symptoms as those reported by Dr. Cantor—sudden pyrexia, severe frontal headache, increased pulse rate, nausea, and lumbar pain. On the fifth day a roseolar rash appeared on the abdomen, similar in type to the rose spots of typhoid fever, disappearing on pressure, and fading away entirely in three to four days, to be replaced, however, by further crops. The spleen was just palpable, but there were no abdominal symptoms, and an examination of the faeces revealed no organisms of the typhoid-paratyphoid group, nor other definitely pathogenic intestinal type, and no parasitic ova or cysts. Serum reactions proved negative to typhoid, both paratyphoids, and to *Bacillus abortus*.

The blood picture, which is of peculiar interest, is as follows: red corpuscles 4,700,000 per c.mm., white corpuscles 10,000 per c.mm., haemoglobin 88 per cent., colour index 0.9. Corpuscles normal in type, and no suppression of platelets. Differential count: neutrophils 36 per cent., lymphocytes 57 per cent., hyalines 7 per cent., eosinophils and basophils 0; 4 per cent. of the lymphocytes are hyperchromatic.

The temperature, as will be seen by the accompanying chart, came down by lysis at the end of ten days, but

there have been periodical rises every second or third day since that time.

Up to this point it may be said that the case has differed in no important characteristic from the obscure exanthem of Drs. Cantor and Shulman, but the interesting fact to be added is that on the fourteenth day there appeared a definite enlargement of the lymphatic glands, particularly the occipital group and the chain of glands along the posterior border of the sterno-mastoid. The axillary and inguinal groups have also been enlarged to a less extent. The tonsils have been clear throughout the attack, though there has been some vascular congestion of the fauces.

The presence of these glands and the characteristic lymphocytosis would certainly suggest that this is a definite case of glandular fever, and it raises the question whether Dr. Cantor's cases were not of the same nature.—I am, etc.,

Lingfield, June 3rd. HAROLD BALME, M.D., F.R.C.S.

SIR,—I am much indebted to the notes on glandular fever which have recently appeared in your columns, and venture to give my experience in three cases (mother, daughter, and housemaid) as I think it most important to make it generally known that we are having at present an epidemic of an infectious disease—glandular fever with roseolar rash—an accurate description of which is not to be found in the textbooks.

The rash is apparently a regular symptom in this epidemic. It corresponded in my cases exactly to that described as an "obscure exanthem" by Drs. Cantor and Shulman in your issue of May 24th (p. 976). The spots and papules are very definite, but may be easily overlooked, as they are not always numerous and are only present for a few days during the first two to three weeks of the illness.

I found no lymphocytosis on the second day of the fever. Later, the blood picture as well as the glandular enlargement reminded me of rubella. Characteristic is the large number of atypical lymphocytes (big cells with pale protoplasm and blue granules, and "piasma cells" with blue-stained protoplasm and eccentric nucleus). I saw in two cases typical large lymphocytes with two nuclei. Culture from lymph glands proved sterile.

R. R. Spencer reported upon a similar epidemic in America in 1926 (*United States Public Health Reports*, 41, 2181).

The diagnosis is easy if attention is drawn to the prevalence of this disease, and I hope that we shall soon learn more about the epidemiology, etiology, and, perhaps, a specific treatment.—I am, etc.,

London, W.1, June 7th. F. E. LOEWY.

ETIOLOGY OF RHEUMATIC DISEASES.

SIR,—Dr. L. C. Dundas Irvine, commenting on the etiology of rheumatic diseases (*Journal*, June 7th, p. 1075), remarks that he believes that, in addition to any focus of infection, there is some other necessary factor, and makes a point that many of his patients have noted their first symptoms within a month or two of a normal confinement, and therefore considers that there must be some ovarian deficiency in these cases.

At the Bath Conference on Rheumatism, in May, 1928, I particularly emphasized this point in a paper on "The endocrine factor in rheumatic disease,"[1] giving three main reasons:

1. That these cases of atrophic arthritis are associated with the advent of menstruation, the child-bearing period, and pregnancy.

2. That the balance of the endocrines is more unstable in the female, and the previous history of these cases frequently reveals enlargement of thyroid, a family history of Graves's disease, or delayed menstrual onset; and, if pregnancy has occurred during the course of the disease, the patient will frequently state that all the symptoms were relieved only to return with fresh vigour during the puerperium.

3. That in cases of intermittent hydrarthrosis the symptoms improve very much, or entirely disappear, during pregnancy.

We are told that during pregnancy the stimulation of the secretion of pituitrin by the internal secretion of the ovary is arrested by that of the corpus luteum until the time is ripe for the uterus to contract and the milk to flow. It appears to me that it is well worth considering whether the inhibitory action of the corpus luteum on the posterior pituitary has any part in the amelioration of the arthritic symptoms during pregnancy. There may also be some association with the presence of the placental secretion. There must be some physiological reason why the female in animals eats the placenta, or why, as I have been informed, the peasant mother does likewise in some parts of the Continent.—I am, etc.,

Harrogate, June 9th. G. L. KERR PRINGLE.

ASTHMA AND ADRENALINE.

SIR,—As a result of previous correspondence on this subject I have been asked on several occasions how it is that I am not in favour of the use of adrenaline in asthma when there is a general consensus of opinion that it is the most successful drug to use. My answer is that I am entirely in favour of its use, and agree with what Dr. Hurst has said about it. The only way in which I differ is about the method of its administration. There are two courses open: one is to allow the suprarenal glands to exhaust themselves, and then to administer adrenaline by hypodermic injection; the second is to conserve the supplies of adrenaline in the suprarenal glands by controlling their output. I suggest that the second method has some advantages over the first. We must not forget that Cannon has shown that the emotions of fear and anger cause a copious flow of adrenaline. But there is another unnamed

[1] *Rheumatic Diseases*, p. 34.

emotion which causes the same phenomenon. It is the "anticipation of exertion," and in its most acute form is known to rowing men as "rowing needle." It is very common. These emotions are most frequent in persons of the highly strung constitution which is one of the earliest observed components of the asthmatic diathesis. If they are allowed free and uncontrolled sway they are bound to produce frequent suprarenal exhaustion. This phenomenon is called "neurasthenia" or "nervous exhaustion" by neurologists.

The method I have adopted, in addition to treating the nasal "trigger," is one which is recommended by Sir Maurice Craig. That is to say, in adults I give a daily dose of 5 grains medinal *nocte*, continuing until the nervous system has quietened down. In children a dose of potassium bromide, 5 grains, dissolved in water, at the evening meal, is usually sufficient. I have had some admirable results from this treatment.

These drugs are recognized by all the leading neurologists to be *not only harmless, but also beneficial in* patients of this diathesis. For physiological confirmation of this method I am indebted to Professor McDowall, who tells me that under the influence of drugs of the veronal type dogs actually store up reserves of adrenaline in the suprarenal glands.—I am, etc.,

London, June 3rd. H. MORTIMER WHALEY.

EPIDEMIC CATARRHAL JAUNDICE: THE INCUBATION PERIOD.

SIR,—The excellent description of an epidemic of catarrhal jaundice by Dr. W. N. Pickles in the *Journal* of May 24th (p. 944) prompted me to look up a few rough notes I had made at the time of a similar, but much smaller, epidemic in this village in 1927. At that time the epidemiology of this condition was obscure and the incubation period uncertain (see Ministry of Health Report on Public Health and Medical Subjects, No. 42, 1927, pp. 8, 9). Dr. Pickles's observations throw considerable light on these important questions, and as a study of my notes amply confirms his conclusions, I have thought a brief review of my cases worthy of record.

The accompanying table has been compiled from my notes. In some of the cases the dates of onset are possibly a day or two late, being really the dates of my first visit; a few of my records are incomplete on this point.

Case No.	Patient.	Sex.	Age.	Date of Onset of Illness.
				1927.
1	W. L.	M.	7	May 9th.
2	A. L.	M.	7	June 3rd.
3	G. T.	F.	4	June 7th.
4	M. E.	F.	6	June 8th.
5	D. K.	F.	12	June 9th.
6	N. C.	F.	8	June 10th.
7	Mrs. B.	F.	32	June 11th.
8	G. F.	M.	5	July 6th.
9	H. C.	M.	5	July 6th.
10	D. L.	F.	11	July 6th.
11	D. C.	F.	16	July 12th.
12	Miss R.	F.	21	July 14th.
13	E. T.	F.	15	July 14th.
14	M. T.	M.	24	July 15th.
15	G. S.	F.	10	July 15th.
16	G. G.	F.	4	July 20th.
17	C. T.	M.	17	August 23rd.
18	S. T.	M.	19	October 24th.

The similarity in epidemiology between this and the Wensleydale epidemic is at once obvious from the table. Here the cases occurred in crops at approximately monthly intervals with no fresh cases in the intervening periods. In a few instances the incubation period can be stated more exactly. Patients 1, 2, and 10 are respectively twin brothers and their sister, and the intervals between their attacks were twenty-five and thirty-three days. Patients 14 and 17 are brothers, and their illnesses were separated by a period of thirty-nine days. There were no other instances of multiple infection in one household. Presumably an undiscovered patient linked cases 17 and 18, who are cousins, and whose illnesses were separated by an interval of almost exactly two months. My cases would thus suggest an incubation period of about one month, but varying from twenty-five to thirty-nine days.

The clinical features of the cases conformed to the typical textbook type, and gave no difficulties in diagnosis. The cases were all mild, and never caused any anxiety. A point of some importance is that two of the adults affected were school teachers, which emphasizes the role of school segregation in the spread of the epidemic.—I am, etc.,

Owston Ferry, Nr. Doncaster. S. ERDHEIM, M.B., Ch.B.

HARE-LIP AND ITS TREATMENT.

SIR,—I should like to reply to some of the points raised in the *Journal* of May 3rd (p. 840) by Mr. T. Pomfret Kilner in criticism of my recent article on the above subject (April 19th, p. 732).

I am aware of the importance of obtaining sound muscle union as well as accurate skin approximation, and Mr. Kilner is correct in his surmise that the muscle layer is included in the silkworm-gut sutures passed deeply into both sides of the lip. I have not used buried catgut sutures as *I fear they would so often become infected, and either work* out through the skin margin or cause deep suppuration, much to the detriment of the subsequent scar; neither have I tried the end-on vertical mattress suture which Mr. Kilner uses, and which I believe is also largely used by Dr. Vean of Paris. Though I have not seen this stitch used it seems to me that with it it would be difficult to be sure that the different layers of muscle were in accurate approximation.

As regards the anaesthetic, I have not been inconvenienced by the proximity of the anaesthetist during the operation, and, owing to the position of the child's head and the constant gentle sponging-out of the pharynx—sometimes with the help of a suction apparatus—I have had practically no trouble from the child's inhaling blood through the glottis. I personally should rather object to putting a tube into the trachea of a young baby for fear of the possibility of setting up broncho-pneumonia or other respiratory trouble. I must say that I have never been inconvenienced in any way, and can hardly detect the smell of the anaesthetic in the slight expirations of a young infant.

Mr. Kilner also criticizes the extensive separation of the soft tissues from the bone; in my article I mentioned extensive undercutting only in cases where the separation of the parts was unduly wide, such as in complete double hare-lip with prominent displaced pre-maxilla, or where there had been a previous and unsuccessful attempt at closure, so as to bring the parts together with as little tension as possible, which is essential if successful closure is to be made: one naturally moulds the pre-maxilla in the unilateral cases as well as in the bi-lateral when it is badly displaced.

I have not practised the method of wiring of the alveolar margins as I have found that moulding and closure of the lip over the prominent part is sufficient practically to close the gap in the alveolus in almost every case: moreover, it seems to me that the presence of a *strong wire in contact* with the unerupted tooth buds for a few weeks must have a very deleterious effect on them.

Since the article was published I have, among subsequent cases, had one which must be very rare indeed and which was the first of its kind that I have seen—namely, a baby with a complete double hare-lip and a prominent displaced pre-maxilla, but with no cleft palate of any kind behind; the gap in the lip on either side was very wide. In operating on this case I had the greatest difficulty in closing the lip, as there was no cleft in the palate in which to push the pre-maxilla, and I was strongly tempted to remove it; only very extensive undercutting enabled me to bring the edges of the lip together in front of the pre-maxilla.—I am, etc.,

Manchester, June 5th. GILBERT B. WARBERTON.

UNDULANT FEVER.

SIR,—My committee has recently appointed a subcommittee to consider what steps, if any, are necessary for the prevention of undulant fever in the borough, and we are empowered to confer with an eminent local veterinary surgeon on the subject.

It is evident from some of the letters recently published in the *British Medical Journal* that the matter should be taken seriously, and I should be grateful if any of your readers, having knowledge of the subject, would write to me giving their views.—I am, etc.,

G. H. R. HOLDEN, M.D.,
Chairman of the Reading Health Committee.

8, Bath Road, Reading, June 9th.

PARALDEHYDE BEFORE AND AFTER ANAESTHESIA.

SIR,—Paraldehyde as an adjuvant to anaesthesia has been given a very good trial by Dr. Hugh R. Phillips, and his statements in the *British Medical Journal* of February 15th (p. 279) are illuminating; the results here proffered are merely accessory to his.

My experience of the *pre-anaesthetic* administration of paraldehyde has been purely in connexion with laboratory animals. The method has, however, had a most extensive trial in the department of human physiology and pharmacology at the Adelaide University, and our results have been so good that all previous methods have been abandoned. The animal mainly used is the Australian rabbit. A dose equivalent to 10 c.cm. of paraldehyde per kilogram of body weight is introduced into the stomach by means of a No. 15 French catheter one hour before starting ether anaesthesia. The results have been excellent and the fatalities are negligible, especially when compared with earlier procedures. Our former methods were pre-anaesthetic injections of luminal or amytal, or no pre-anaesthetic preparation, open ether without preliminaries being given, or A.C.E.3.

In regard to the *post-operative* administration of paraldehyde, I have for some time endeavoured to prevent dehydration due to vomiting, etc., by giving patients immediately after operation 20 oz. of normal saline solution, with two to three drachms of the drug per rectum. The same amount of saline solution is given four hours later, with 1½ to 2 drachms of paraldehyde, and if retained this is repeated after a further four hours. The result has in general been gratifying. Compared with cases in which this after-treatment has not been used, the results have been satisfactory in many respects. The advantages may be summarized as follows: reduction of vomiting, less tendency to abdominal discomfort and intestinal distension, less post-operative dryness of the mouth, easier nursing. If the operation is performed in the morning the patient usually goes through to the following morning with very little trouble. A considerable amnesia is produced. The disadvantage is that the paraldehyde is excreted through the lungs for a long time and is rather objectionable, but the same might be said of ether.

Thus the pre-operative paraldehyde treatment of Dr. Phillips might well be continued into the post-operative period without fear of ill effect, though in that event the post-operative dose of paraldehyde might be reduced, and perhaps the patient should wait for an hour or so after the operation before the first post-operative dose of paraldehyde is given.—I am, etc.,

R. FRANCIS MATTERS, M.D., M.S., F.R.C.S.Ed.

Department of Human Physiology, University of Adelaide, April 10th.

STERILITY IN WOMAN.

SIR,—The interesting discussion on this subject brings to my mind the following case. I was informed by a man, well known to me, and whose word I have no reason to doubt, that he had had frequent illicit connexion with an unmarried woman over a period of one or more years, without pregnancy resulting, although no precaution of any kind was taken. Each married about the same time, and each became a parent just under one year from the date of marriage. No doubt the majority of cases of sterility are due to some mechanical defect in the female sexual organs, or to some physiological or pathological defect in the ovary or testicle respectively, but this case seems to suggest that there is some other factor not yet identified. One also knows of cases where pregnancy only occurred after ten or more years of married life. Such cases can hardly be due to an inherent defect in either party, as a rule, but may be attributable to what I might describe as psychological reasons; perhaps some gynaecological expert would contribute his views.—I am, etc.,

D. J. GAIR JOHNSTON.

Birkenhead, May 26th.

PERIANAL RESISTANCE TO INFECTION.

SIR,—I should be much obliged if someone would explain why it is that wounds in the region of the anus and rectum seldom become infected. I read in the *Queen Charlotte's Practice of Obstetrics* (p. 405) that the perianal region is "the most heavily infected surface of the body," and a great source of danger to the placental site. Yet the wound after operations such as for anal fistula or for piles rarely causes trouble, though it is exposed to contamination by faecal discharge.—I am, etc.,

H. W. WEBBER.

King's Tamerton, Plymouth, June 4th.

PAYING WARDS IN HOSPITALS.

SIR,—In the *Times* of May 30th there was a letter under this heading from Dr. Alfred Cox about which I should like to say a few words. The letter was one of grateful thanks to the *Times* for a leading article upon the same subject in the issue of May 29th.

The writer of that article was pleading for the many practitioners who, as he put it, were often from force of circumstances not upon the staff of any hospital. He welcomed the idea that with paying wards attached to a hospital these practitioners would be able to give institutional treatment to patients who could not afford the charges of an ordinary nursing home. In the opinion of the writer of that article, it is quite clear that patients occupying the paying wards should be free to choose their own doctor, and should not necessarily be under the care of a member of the visiting staff of the hospital. The paying wards would, in fact, supply the needs of a nursing home for those of moderate means.

From Dr. Alfred Cox's letter it would appear that he takes an entirely different view of the matter. He speaks of the patient in the paying ward as being under the responsible care of a member of the hospital staff in association with the private practitioner, who should have access to his patient at all times, and have such share in the treatment as might be agreed upon. Dr. Cox, while allowing the patient in a paying ward to select his own medical attendant, says: "If the treatment should involve the application of special skill the practitioner undertaking that treatment may be required to satisfy certain conditions ensuring that he has the necessary experience and training" to perform them.

Now, Sir, this seems a most remarkable requirement, for it means that the medical attendant, in order to treat his private patient in the paying ward, must, after having "satisfied the examiners" and received his licence to practise, subject himself to an inquisitorial examination and inquiry before he is allowed to use his skill upon his patient. If a policy such as this is to be adopted in the management of paying wards in or attached to general hospitals it is not likely to make for the best interest of the patient or the good working of the system. Something much more liberal and on the lines suggested in the *Times* article would commend itself far more to all concerned.—I am, etc.,

PRESTON KING, M.D.

Bath, June 4th.

*** Dr. Preston King may be referred to the relevant part of the British Medical Association's Hospital Policy, as set out in the *Supplement* of April 19th, 1930 (p. 157)—Appendix B, "Conditions of Admission and Treatment of Private Patients in Hospital."

Obituary.

R. McKENZIE JOHNSTON, M.D., F.R.C.S.Ed.,

Consulting Surgeon to the Ear and Throat Department, Royal Infirmary, Edinburgh.

THE death took place in a nursing home in Edinburgh, on June 1st, of Dr. R. McKenzie Johnston, who was for many years well known in Edinburgh as a specialist in diseases of the ear, nose, and throat. He was born in Edinburgh in 1856, his father, the late Henry Johnston, having been a surgeon to the Honourable East India Company. Several of his brothers have also attained to distinction in fields other than those of medicine, including Sir Duncan A. Johnston, whose work in connexion with the Ordnance Survey is well known, and who since the war has done a great deal of good work for disabled men; Lord Johnston, who recently retired from the Bench; and Mr. William C. Johnston, Deputy Keeper of the Signet.

Robert McKenzie Johnston was educated at Edinburgh Academy and at Clifton College, and after the usual course of medical study in Edinburgh he graduated M.B., C.M. in 1881, proceeding M.D. in 1883. In 1882 he held the post of resident physician to the late Dr. John Wyllie, and was senior president of the Royal Medical Society of Edinburgh. In 1884 he became a Fellow of the Royal College of Surgeons, but conducted a general practice in Edinburgh till 1890, when he adopted diseases of the ear, nose, and throat as a specialty. For several years he held the post of assistant surgeon, and later, for three years, of surgeon in charge of the ear and throat department of the Edinburgh Royal Infirmary, resigning this in 1906, when he was appointed by the managers consulting surgeon to that department. Laid aside for a time from active work by reason of an affection of the throat, he was obliged, following upon an operation, to give up active professional work, but he continued almost to the time of his death to interest himself energetically in public work in various directions. He was the author of the article on "Acute inflammation of the middle ear" in the *Encyclopædia Medica*, and had published numerous contributions to the periodical literature of his special subject, including a report on "A case of intratracheal tumour" in the *Edinburgh Medical Journal* of 1886; on "The use of papain in ear disease" in the same journal for 1890; and a record of a "Rare case of nasopharyngeal tumour" in the *British Medical Journal* of 1888.

Dr. McKenzie Johnston was one of the founders of the Laryngological Society of the United Kingdom, and of the Otological Society of London, and he took a deep interest in the work of the British Medical Association. In this Association he acted as vice-president of the Section of Laryngology and Otology at the Annual Meeting held in Edinburgh in 1898, and subsequently was president of the Section of Laryngology, Otology, and Rhinology in the meeting held in Exeter in 1907. He had two periods of office as a member of the Central Council of the Association, in 1904–5 and 1909–10, and he was a valued member of the Building Subcommittee of the Association in connexion with the rebuilding of its Strand premises in the year 1907–8. In local medical affairs in Edinburgh he took an active part, and his advice was eagerly sought. Thus he was for many years surgeon of the Edinburgh Ear and Throat Dispensary, and his eminence in his specialty was recognized by the Royal College of Surgeons, which appointed him its president in the year 1917. For many years after ceasing to be a member of its staff, he acted as a manager of the Royal Infirmary of Edinburgh, where his services were particularly valuable during the later stages of the war. From 1903 to 1928 he was a member of the University Court of the University of Edinburgh. Other positions held by him were those of a governor of Fettes College, and a member of the Royal Company of Archers (the King's Bodyguard for Scotland).

Dr. Johnston had been married to a daughter of the late Mr. Henry Younger, D.L., of Benmore, Argyllshire, by whom he was predeceased in 1919, and he is survived by three sons and a daughter. The interment took place in the Dean Cemetery, Edinburgh, on June 3rd, after a funeral service in St. John's Episcopal Church, Princes Street, which was attended by a large assemblage of personal and professional friends, including a deputation from the Royal College of Surgeons.

DR. A. LOGAN TURNER writes:

After a brief period spent in general practice, Dr. McKenzie Johnston turned his attention to the study of diseases of the ear and throat at a time when specialists were not so numerous as they are to-day. In the spring of 1890 he was appointed assistant surgeon to the ear and throat department of the Royal Infirmary of Edinburgh, then in the charge of Dr. Peter McBride. At this time there was no accommodation for the treatment of in-patients, and the necessity for beds for this purpose was becoming increasingly clamant. Accordingly, in 1891, six special beds were provided in the Infirmary for ear and throat cases. For thirteen years Dr. Johnston held the position of assistant surgeon, until, in 1903, on the retirement of Dr. McBride, he became full surgeon, and succeeded to the appointment of university lecturer on diseases of the larynx, ear, and nose. With the slow but steady growth of the department during Dr. McBride's tenure of office, and with the establishment, in 1897, of the lectureship, the increasing amount of work gradually outgrew the accommodation hitherto assigned to it. A separate pavilion was accordingly built and equipped with twenty-four beds, with commodious out-patient rooms and a lecture theatre. This was completed in 1903, and was occupied for the first time by Dr. McKenzie Johnston shortly after his appointment as surgeon. He brought to the equipment of the new department an essentially practical mind and an intimate knowledge of what was necessary in the installation of electrical equipment and the appliances required for the conduct of the work.

After thirteen years of diligent and unremitting attention to duty as assistant surgeon, and after holding for a brief period the senior position which he had deservedly merited, his professional career was unfortunately brought to an end by an illness which incapacitated him for further usefulness as a teacher. Realizing that his disability would act as a hindrance to his powers as a lecturer, he decided to demit office rather than jeopardize the teaching of his subject in the medical school. Consequently, in July, 1926, he resigned his hospital and university appointments. Dr. Johnston faced the situation with admirable fortitude, and after a long period of rest he returned to work, applying his energies in other important directions. For nearly twenty-five years he took a very active part in various administrative posts, and the Royal Infirmary, the University, and the Royal College of Surgeons of Edinburgh reaped the benefit of his administrative and financial ability. In 1907 he joined the Board of Management of the Royal Infirmary, and for twelve years served the institution as a manager, giving ungrudgingly much time and attention to its affairs. For over twenty years he was an active and valued member of the University Court. As secretary to the College of Surgeons for ten years, he devoted himself with untiring application to the duties of that office, and his election as president of the College in 1917 was an honour duly merited by his previous services.

JOHN BUCKLEY BRADBURY, M.A., M.D., F.R.C.P.,

Downing Professor of Medicine in the University of Cambridge; Consulting Physician to Addenbrooke's Hospital.

PROFESSOR BRADBURY'S death on June 4th, after a week's illness, breaks a link with the past; he was a survivor of the old apprentice system, had lived continuously in Cambridge since 1866, at one time or another had taught most of the subjects that medical students have to learn, was one of the oldest resident members of the University, and since 1928 had been the senior Fellow of the Royal College of Physicians of London.

Born on February 27th, 1841, at Saddleworth in Yorkshire, he was the eldest son of John Bradbury, merchant; both his father and mother died comparatively early, and he had not any long-lived ancestors. At the age of 17 he became an apprentice to a medical man, and in the Easter

term of 1862 entered Gonville and Caius College, but early in the following year migrated to Downing College, where he had gained a scholarship thrown open to the University and tenable until the standing for the degree of M.A., if the holder obtained a first-class in the tripos. In 1864 he was placed second in the first class of the Natural Sciences Tripos, one of the examiners being P. W. Latham, his private tutor, future colleague, and predecessor in the Downing professorship. After working at King's College Hospital he returned to Cambridge in 1866, and was appointed lecturer on comparative anatomy at Downing College. In the following year he took the final M.B., and in 1870 proceeded to the degree of M.D. It may be interesting to quote his opinion of the examinations, which he thought were more difficult then than now. At that time there were two M.B. examinations; the subjects of the first were selected passages from the medical classics —Hippocrates, Aretaeus, and Celsus—botany, chemistry, comparative anatomy, materia medica and pharmacy, human anatomy, physiology, and pathology; the second examination comprised medicine, surgery, midwifery, and jurisprudence.

After lecturing for ten years at Downing he became lecturer on anatomy and physiology at Caius until 1880, when he gave up lecturing on natural science, as the claims of private practice were becoming insistent. On Professor H. J. H. Bond's resignation of the physiciancy at Addenbrooke's Hospital in 1869 Bradbury was elected, and held this office for the remarkably long period of half a century, his tenure having been prolonged on several occasions. For many years he had an extensive practice in and around Cambridge, and, indeed, never gave up work entirely, for on the day of his fatal seizure with hemiplegia and aphasia a patient came to see him. In the early days of waiting, when he was beginning to despair and thinking of going elsewhere, he gained considerable reputation for the correct diagnosis of hydatid disease of the liver, a condition formerly common in the district, in a case regarded by a senior as malignant. In 1872 he succeeded Sir George Paget as Linacre Lecturer at St. John's College, and gave lectures on pathology until 1884, when the late C. S. Roy was appointed the first professor of pathology in the University. He was succeeded in 1904 by Sir Donald MacAlister in the Linacre Lectureship, which in 1908 became an annual appointment given to extra-university authorities, the first being Sir William Osler.

In 1894, after twenty years' tenure, P. W. Latham resigned the Downing Professorship of Medicine, and Bradbury began his long occupation of this chair. He was fortunate in attracting as his assistants Professor C. R. Marshall, now of Aberdeen, in 1894, and in 1899 W. E. Dixon, now reader in pharmacology in the University. At the Royal College of Physicians of London, of which he became a Member in 1867 and a Fellow in 1874, he was Bradshaw Lecturer in 1895, taking as his subject "Some new vaso-dilators," Croonian Lecturer in 1899, "On some points connected with, sleep, sleeplessness, and hypnotics," and councillor 1899–1901. He also wrote the article on disorders of sleep in the first edition of Allbutt's *System of Medicine* (1899, vol. vii), and a book on vertigo (1870). Some four years ago he sustained an accident to an eye; recently his sight failed, and he had become somewhat deaf. He was twice married, and is survived by his second wife, [illegible] in the medical profession, and two daughters, one of [illegible] perhaps as a sister at Addenbrooke's Hospital. The funeral [illegible] at 3.30 [illegible] on June 7th, at St. Mary's the [illegible] is given.—[illegible] Street, Cambridge.

[illegible] R. F.

[illegible] 10th.

H. COOPER PATTIN, M.D.

[illegible] Medical Officer of Health for the [illegible], D.P.H.,

announced in our last issue, [illegible] WOM City of Norwich.

[illegible] years medical officer of heal[illegible]ion on Dr. Cooper Pattin,

died at Torquay on May 30th [illegible] was [illegible]th for the city of

[illegible] me months.

Cooper Pattin was born in 18[illegible]ord I[illegible]h after an illness

[illegible] llege, Cambridge, as a medical st[illegible]illicit [illegible]

[illegible] h honours in the Natural Science[illegible] of one[illegible]2, and entering

his medical course at St. Thomas's [illegible]ugh [illegible]dent graduated

[illegible] about[illegible]s Tripos, com-

[illegible] Hospital [illegible]

1889 he obtained the M.R.C.S. and L.R.C.P. diplomas, and graduated M.B., B.Ch. at Cambridge in the following year. He took the Cambridge D.P.H. in 1891, and proceeded to the M.A. and M.D. degrees in 1899. Having decided on a career in the public health service, Dr. Pattin was appointed medical officer of health for Norwich in the late nineties, and continued to hold that post with distinction until he retired four years ago under the age limit. On relinquishing office he received public expressions of gratitude and good will from the corporation and citizens of Norwich.

After his retirement Dr. Pattin travelled round the world, and in February, 1927, acted as official delegate of the British Medical Association at the Australasian Medical Congress held at Dunedin, New Zealand. In former years he had taken an active part in many annual meetings of the Association, serving as honorary secretary of the Section of Public Medicine at Carlisle in 1896, and as vice-president of the Section of State Medicine at Ipswich in 1900. He had long been an active and prominent member of the Society of Medical Officers of Health, and held office as president in 1909–10. He was also a past-president of the Ipswich Medico-Chirurgical Society. Outside his official work he had many interests. He was a lover of books, plays, music, and pictures, and spent nearly all his vacations in travel abroad.

The editor of the *Medical Officer* allows us to quote the following extracts from a personal tribute written by Sir Arthur Newsholme:

Dr. Harry Cooper Pattin will be remembered by his many friends and acquaintances for qualities which enlisted both interest and regard. When I visited him in Torquay in January of this year he was evidently failing in health, but his so early death could scarcely be anticipated. It is regrettable that this occurred in a place remote from his old colleagues and friends of the Society of Medical Officers of Health and of the ancient city of Norwich—as he delighted to describe it—so that few of them could pay him the last tribute of respect and regard. My first acquaintance with him originated in a letter received when he was elected to the Norwich post, announcing in his own special way his intention to visit Brighton to ascertain what was being done there. I need not attempt to describe his official work. Others can do this with more complete local knowledge than I possess. He often had difficulties to overcome—as we all had—but his tact and self-possession and the absence of bluster helped him to secure the reforms advocated by him. His colleagues of the Society of Medical Officers of Health elected him their president for the session 1909–10, and he held the post with dignity and success.

Some of my most pleasant memories are of bicycling expeditions in France, visiting a succession of cathedrals, visiting and revisiting the châteaux of the Loire, etc., with Pattin. He was well informed on all general subjects, and loved to study and realize history in its association with the localities concerned. At home the same characteristics emerged. Occasionally he would announce an impending visit to the London house of his friend. This would mean his appearing about midnight, after a theatre matinée and an evening concert or theatre. A few days later would come a press cutting from the *Eastern Daily Press* containing an admirable appreciation of what he had seen or heard. Some of these articles, and others describing his travels, were collected in a volume entitled *The Excursions of an Improvident Philosopher*, which contains some of his most characteristic writing. He affected a literary style of his own, which reminded one somewhat of Sir Thomas Browne's writings. It made him happy to invent a new word, or to use an almost obsolete word in an unusual, but quite legitimate, manner. Among his other writings were *Ritual of Temperance*, *Obiter Scripta*, and *Rummage*; in all of which Pattin's special views on life emerged. They showed much wisdom in a light and easy form. But although it would appear from the above that Pattin had much that characterizes a *dilettante*—of a choice type—it must not be assumed that his professional work was shirked or belittled, and the record of Norwich during his period of office is adequate proof of this. He was a choice spirit, and his memory is one of life's treasures.

A. F. R. WOLLASTON, D.S.C., M.A., B.CH.,

Fellow and Tutor of King's College, Cambridge.

THE deplorable affair at Cambridge, on June 3rd, when Dr. A. F. R. Wollaston was shot dead in his rooms at King's College by an insane undergraduate, has caused grief in many circles, and not least among his friends in the medical profession, who loved him for his personal qualities as much as they admired him for his achievements as explorer and naturalist.

Alexander Frederick Richmond Wollaston was born in 1875, and came of a family which produced many distinguished scholars and men of science, notably William Hyde Wollaston, M.D., F.R.S., the eminent physiologist, chemist, and physicist (1766–1828). From Clifton, where his father was a well-known house-master, he went to King's College, Cambridge, graduating B.A. in the Natural Sciences Tripos of 1896, and thence to the London Hospital. He became M.R.C.S., L.R.C.P. in 1903, and afterwards took the M.A. and B.Ch. degrees. Though practice never appealed to him he acted as medical officer to several of the exploratory parties of which he was a member, and throughout the war he served as temporary surgeon R.N., being mentioned in dispatches and receiving the Distinguished Service Cross. Wollaston's ability as an all-round naturalist was widely recognized in the world of science, and his literary gift enabled him to write of his travels and discoveries with charm and precision. Wollaston Peak, on Mount Ruwenzori, records his ascent in 1905 as a member of the British Museum expedition to Central Africa. On the second of his two journeys in Dutch New Guinea he acted as leader of the British Ornithological Expedition, acquiring much ethnological information and bringing home many valuable specimens of flora and fauna. For these services he received, in 1914, the Gill memorial award from the Royal Geographical Society, which after his return from the Mount Everest expedition in 1922 awarded him also the patron's gold medal.

Ten years ago his College elected Wollaston to a supernumerary fellowship, and at the close of 1928 he was re-elected a Fellow and appointed tutor in succession to Dr. J. H. Clapham. This post, which brought him into intimate touch with all the undergraduates of King's, was most congenial, and his friends looked forward to many happy and successful years of work for the great foundation which he loved so well. Wollaston was a man of outstanding character and attainments, and his death, in the full tide of active service for others, is regarded by all who knew him as nothing short of a calamity.

T. I. CANDY, M.B., D.M.R.E.,

Radiologist to the Royal Gwent Hospital, Newport, Mon.

NEWS of the death of Dr. Candy at Newport, Monmouthshire, on June 1st, after a very brief illness, was received with profound regret and sorrow by the medical profession in South Wales and Monmouthshire, and also among the community in which he lived and worked.

Thomas Ignatius Candy was born in Londonderry in 1892, and received his early education at St. Columba's College in that city. He then entered Queen's College, Belfast, and graduated M.B., B.Ch., B.A.O. of Queen's University in 1918. After some time spent in general practice and subsequently in post-graduate study, he obtained the diploma in radiology of Cambridge University in 1920. He was formerly medical superintendent of the War Pensions Hospital, Birmingham, clinical assistant to the *x*-ray department of King's College Hospital, and deputy physician in charge of the *x*-ray department at Charing Cross Hospital. He was appointed honorary radiologist to the Royal Gwent Hospital, Newport, in 1922. He created and organized this special department and rapidly made a name for himself as a skilled investigator; he applied himself particularly to establishing the value of skiagrams taken at various stages of pregnancy with the object of discovering *malpositions of the foetus in utero*. He published some monographs and several papers of great merit in the medical press, and translated *Lenk's Index and Handbook of X-Ray Therapy* (Oxford Medical Publications).

Candy gained the complete confidence of the general practitioner, and was able to help him in the elucidation of many difficult problems; he frequently gave expert evidence on workmen's compensation cases at Monmouthshire County Court. In addition to excelling in his specialty he was a first-rate photographer, and spent much of his spare time in making films for production as moving pictures. He was a Fellow of the Royal Society of Medicine; a member of the executive of the Monmouthshire Division of the British Medical Association, serving as secretary of the Section of Radiology at the Annual Meeting in Cardiff in 1928; and secretary of the Newport Medical Society.

Dr. Candy leaves a widow and four young children, with whom much sympathy is felt. A Requiem Mass was celebrated at St. Mary's Catholic Church on June 4th, and was well attended by people of every section of religious belief, indicating the esteem in which he was held.

"S. H." writes: I have known Dr. Candy since his advent to Newport; his death from toxaemia at the early age of 38 is a blow to his fellow practitioners and a sad end to a life full of promise and of service to others. Candy was a most lovable man—simple, sincere, and absolutely free from guile, with the heart of a child; his characteristics received outward expression in his pleasant, smiling face. Everyone loved him, yet he never sought popularity. He passed through life quietly and steadily, doing what came to his hand with all his might. His work was marked by industry and painstaking thoroughness. He made the most of the day. "The honour of the day is forever the honour of that day. It goes into the treasury of things that are honestly and completely ended and done with." One may reflect with the poet Horace on the uncertainty of life:

> "Quis scit an adjiciant hodiernae crastina summae
> Tempora Di superi?"

DR. ROBERT CAMPBELL GILROY, who died on April 23rd, studied medicine at Glasgow University, where he graduated M.B., C.M. in 1885. Having held an appointment as house-surgeon to the Paisley Infirmary, he went to Birmingham, where he was engaged in practice till the outbreak of the Boer war, when he joined the Army and sailed for South Africa. After the war he practised in Standerton for a few years, and then returned to England, settling in Leicester. There, for many years, he carried on a large practice, from which he retired owing to the state of his health. For a time he stayed in Edinburgh, but eventually went to Paignton in Devon, where he lived in retirement. A colleague writes: Dr. Gilroy inspired respect in those who met him: and all who knew him held him in esteem and affection. He was a well-informed and successful practitioner. By his skill, patience, sympathy, and tact he won the confidence of his patients; and his bright cheery nature, his unassuming disposition, his interesting and informative conversation, combined with his fine powers of description, made him a great favourite with his friends. He leaves a widow, and a son who is in the medical profession.

We regret to announce the death of Dr. HERBERT W. G. MACLEOD, which took place in London on May 30th. Dr. Macleod graduated M.B., C.M. at Edinburgh in 1886, and in the following year was successful in the competitive examination for commissions in the Indian Medical Service. He took part in the Black Mountain expedition, for which he received the medal and clasp. On retirement from the service he returned home, and subsequently proceeded to take the M.D. and B.Sc. degrees at his old university, and later, the M.R.C.P.Lond., engaging in consulting medical practice in Wimpole Street. As he had been greatly interested for many years in the legal profession as well as his own, he began to study law at the Middle Temple, and was called to the Bar in 1913. He was a Freemason of long standing and one of the founders of the King's College School Lodge. He was also a Fellow of the Royal Astronomical Society, and a member of the British Medical Association for many years.

Medico-Legal.

DOCTORS' PARTNERSHIP DISPUTE.

KILLARD-LEAVEY v. O'FLAHERTY.

IN the Chancery Division of the High Court of Justice, before Mr. Justice Bennett, on May 29th, an action was begun by Dr. T. J. Killard-Leavey of Torrington, Devon, against Dr. A. R. O'Flaherty of the same town, with whom he had been in partnership since 1926, for a declaration that a notice given by defendant determining the partnership was void, and for an injunction restraining the defendant from excluding him from the partnership premises. The defendant counter-claimed for a declaration that the notice was valid. A dissolution of partnership by the court was sought by both parties.

Mr. J. E Singleton, K.C., who appeared for Dr. Killard-Leavey, said that both he and Dr. O'Flaherty were nearly 60 years of age. The former, before entering the partnership, had carried on an extensive practice at Southend, which he sold in 1926, preferring a country practice. Dr. O'Flaherty had practised for some years at Torrington before he was joined by Dr. Killard-Leavey. The gross earnings of the practice, partly insurance and partly private, were about £2,000 a year. Difficulties arose between the partners, and in January last Dr. O'Flaherty gave notice dissolving the partnership under a clause in the agreement which stated that if either partner neglected the business or was guilty of flagrant conduct likely to injure it, the other might expel him. He also took down Dr. Killard-Leavey's name from the surgery door. Both parties now wanted the partnership dissolved, but Dr. Killard-Leavey, who had put £1,445 into the business, contended that if the partnership was dissolved under the articles, as defendant claimed the right to dissolve it, he would receive only £450, whereas if Dr. O'Flaherty's charges were shown to be unjustified, and the partnership were dissolved by the court as a result of this action, he would be entitled to at least £1,500 under the agreement. He also desired that the allegations made against him by Dr. O'Flaherty should be publicly refuted. There were sixteen complaints, eleven of which related only to something in the nature of disapproval expressed by the plaintiff of the defendant's treatment.

Mr. Rayner Goddard, K.C., who accepted onus of proof on behalf of the defendant, and opened the case, said that Dr. Killard-Leavey had been guilty of gross neglect, and had committed breaches of the partnership articles. He had not been diligent or faithful to his partner. The allegations concerned inexcusable neglect of patients and criticisms to patients of his partner's treatment. With regard to the latter complaint, in one case when the defendant had diagnosed erysipelas, plaintiff told the patient that he had never had that complaint, but was suffering from shingles. In another, he tore up a prescription given by the defendant. Three specific allegations of neglect were made. It was alleged that after receiving a message that a private patient, a farmer's daughter, six miles away, was very ill, Dr. O'Flaherty being out, Dr. Killard-Leavey refused to go, saying that he knew nothing about the case, and that he would tell Dr. O'Flaherty on his return. In another instance, on being called up at an early hour in the morning, it was stated that he inexcusably declined a call to visit an insurance patient who was liable to heart attacks. In the third case, that of a child suffering from symptoms of appendicitis, it was alleged that Dr. Killard-Leavey, after delaying a visit for several hours, diagnosed chronic gastritis, pooh-poohed the parents' fears, and declined to consult with another doctor whom they proposed. Later, the child was operated upon for appendicitis just in time to save her life.

The Defendant's Evidence.

Dr. O'Flaherty, in giving evidence in support of these complaints, said that he was not questioning Dr. Killard-Leavey's skill, but he was questioning his conduct. He thought it a most serious thing for a practitioner to tear up the prescriptions of his partner. He agreed that he had sometimes called in a second opinion without any reference to Dr. Killard-Leavey.

Evidence was given by the messenger who had summoned the doctor to the case of the farmer's daughter. Dr. O'Flaherty was out, and she drove to the house of Dr. Killard-Leavey, who refused to go, saying that it would be better for his partner to go on his return. The hour was about 8 p.m., and she learned that Dr. O'Flaherty was expected back between 9.30 and 10. Another witness said that when he asked Dr. Killard-Leavey at 1.45 a.m. to attend his son, who had a heart attack, he said: "It is not quite fair to me, is it? Go and give him a hot drink." Witness called in another doctor. The father of the child who had suffered from appendicitis said that Dr. Killard-Leavey told him that he (the father) thought the child much worse than was really the case. He refused to consult with the doctor whom the father proposed to call in. The child was removed to hospital and operated on for appendicitis. Mr. Ellis Pearson said that he operated on the child, who had an inflamed appendix and adhesions. He agreed that it was more difficult to diagnose that condition in a child than in an adult. He had frequently met Dr. Killard-Leavey in consultation, and had no suggestion whatever to make against him in his professional work.

The Plaintiff's Evidence.

Dr. Killard-Leavey, in evidence, said that it was his custom to ask patients about the action of their medicine, and if it was not suiting them he asked if he might change it. Dr. O'Flaherty seldom made discussion possible, and would turn his back and walk off. His remark in the erysipelas case was made without knowing what Dr. O'Flaherty had said.—With regard to the case of the farmer's daughter, he told the messenger that if his partner would not go, he would go himself. He gathered from the messenger's manner that there was no immediate urgency, and that the practitioner who knew the case was the best man to attend. He agreed that he did not take any steps that night to see whether Dr. O'Flaherty had gone. The messenger was mistaken as to the time of her call on him. He looked at the church clock at the time, and it was just upon 9 p.m., and Dr. O'Flaherty was expected back at 9.30. In reply to a further question, he admitted that the church clock was not illuminated, and that it would be difficult to see it at nine o'clock on a November night, but it was possible he had ascertained the time by his own timepiece; he did not think it material. Later he assumed that Dr. O'Flaherty had returned in time to visit the case, otherwise he would have been rung up. With regard to the other case, in which he had been called at 1.45 a.m., he did not see that he could do any good by going; the boy only wanted soothing, and when he called next morning the boy's mother said that he had gone to work, and that she had summoned another doctor. In the appendicitis case he had not been able to find any cardinal symptom of it.

Judgement.

Mr. Justice Bennett, in delivering judgement, said that there was evident incompatibility between the partners, and it was not surprising that before the third year of the partnership the relations became strained. The question to be decided was whether the plaintiff had grossly neglected the business of the partnership or had committed a breach of the articles sufficient to entitle defendant to expel him from the partnership. There were two classes of acts upon which defendant justified his action: (1) negligence in connexion with patients, and (2) conduct calculated to lead the patients of the partnership to think lightly of the defendant by criticizing in a hostile or contemptuous manner the defendant's diagnosis or treatment. With regard to the second ground of complaint, the defendant had failed to prove to his satisfaction that the plaintiff had ever deliberately and intentionally criticized in hostile or contemptuous words the defendant's diagnosis or treatment. With regard to the first ground of complaint, the decision was more difficult. The most serious complaint was with regard to the child who had appendicitis. His lordship had no doubt, after hearing the evidence, that the plaintiff in his conduct of the case fell far short of the standard which either the patient or her parents or his partner were entitled to expect. With regard to the call at 1.45 a.m., he was not prepared to hold that a doctor summoned at that hour and acting as Dr. Killard-Leavey had done, was necessarily guilty of gross neglect of the business of the partnership. One instance of that kind might well be excused as an error of judgement. There remained the case of the farmer's daughter. It was a great pity that Dr. Killard-Leavey, in fixing the time at which he was called to that case, had made an untrue statement about the church clock. He was satisfied that the plaintiff was summoned to the case before 9 p.m., and that he knew something about the case, and possibly thought no great harm would be done by allowing an hour or an hour and a half to elapse before the patient was seen by a doctor. In the judge's view, the practitioner refused to go and see the case because, at that stage of the partnership, he was not disposed to turn out late at night to see one of his partner's patients. His temper got the better of his judgement. There were therefore two cases in which the defendant had satisfied him: in respect to one, the plaintiff had been guilty of neglect, and in respect to the other, he had acted in a way in which he would not have acted if he had kept his temper. But one act of negligence or one error of judgement could not be said to be gross neglect of the business of a partnership. Taking the case as a whole, he was not prepared to hold that the plaintiff had grossly neglected the business. The clause in the articles required proof of some regular course of careless conduct or something in the nature of wilful neglect. He was satisfied that there was no wilful neglect in the case of the child who had appendicitis, also that the plaintiff was not the kind of man who would have been careless of the interests of the patients for whom he was responsible. He was entitled to the declaration which he claimed—namely, that the partnership remained subsisting not-

withstanding the notice. It was clearly a case, however, in which it was quite impossible for the partnership to continue, and the court would make a decree for dissolution in the usual form. Defendant must pay the costs of the action.

On the application of Mr. Goddard, his lordship agreed to allow costs to the defendant for the matters in which he had succeeded—namely, the case of the child suffering from appendicitis and the case of the farmer's daughter.

The Services.

CORRECTION.

BY a regrettable mishap the name of Colonel C. K. MORGAN, C.B., C.M.G., late R.A.M.C., appeared in the list of deaths at page 1003 of the *Army List* for May, 1930, and on the strength of that notification a brief biography was printed in our issue of May 31st, under the heading "Deaths in the Services." We hasten to contradict the announcement. Colonel Morgan's friends will be glad to know that he is now recovering from his recent severe illness.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on June 8th the following medical degrees were conferred:

D.M.—C. R. Croft, Alice E. B. Harding.

UNIVERSITY OF CAMBRIDGE.

AFTER his installation as Chancellor of the University on June 6th, the Right Hon. Stanley Baldwin conferred honorary doctorates in law, science, or letters on H.R.H. the Duke of Gloucester, the American Ambassador (General Dawes), Earl Beauchamp, Viscount Sumner, Viscount Bridgeman, the Right Hon. Arthur Henderson, Sir John Withers, Professor Einstein, Professor Max Planck, Sir John Rose Bradford, P.R.C.P., Sir James Irvine, Professor W. Meyer-Lübke, Professor Lascelles Abercrombie, Sir James Barrie, Mr. Sydney Cockerell, Mr. John Galsworthy, and Professor H. J. C. Grierson.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examination indicated:

THIRD M.B. [illegible] E. Cook, *†K. M. Robert-[illegible] E. F. D. Baker, D. A. [illegible] W. F. Burnett, E. A. [illegible] *Con*beare, W. W. Craner, [illegible] C. C. de Silva [illegible] P. B. P. [illegible] klin, Ruth C. Galletly, [illegible] Harsant, J. C. Hatrick, [illegible] on, C. B. Huss, Phyllis [illegible] Lloyd-Davies, Laura H. Macfarlane, H. G. McGregor, B. R. Medlycott, T. W. Morgan, C. L. Oakley, C. M. Ockwell, R. Oliver, R. A. H. Pearce, G. F. Peters, R. K. Price, Ruth Pumphrey, B. Ram, H. Richards, Margaret P. Roseveare, T. N. Rudd, J. C. Saldanha, R. M. Sargent, J. G. Scaddicg, J. M. Scott, M. D. Sheppard, L. A. H. Snowball, T. T. Stamm, B. Stanley, Sybil M. A. Stanley, W. D. Steel, J. H. Watkin, Margaret M. White, G. P. B. Whitwell, Joyce M. Wigram, R. N. Wilcox, E. G. Wilkins, Margaret D. Wright.

Group I.—T. Back, E. F. Barnardo, F. G. L. Barnes, A. C. Byles, W. H. P. Cant, Rosa E. Chambings, E. E. Claxton, H. J. Croot, C. E. Dolman, Beryl M. Furlong, Mabel E. Grace, Honor E. C. Harvey, H. H. Jackson, Victoria A. King, H. J. Knight, Nellie L. Lanckenau, L. W. Lazarus, Annie M. McGrath, Joyce MacInnes, Eileen M. Massey, Elizabeth T. Mess, Ruth Milne, R. S. Risk, J. B. Robinson, D. Stanley Jones, H. H. Steadman, Muriel H. Steven, Olive C. Watkin, T. H. Wilson.

Group II.—W. L. M. Bigby, A. Caplan, A. G. Carmichael, J. B. George, Bryneilen Griffiths, D. Gwynne-Evans, Mary W. Hamlyn, P. Y. Hicks, R. E. Holmes, S. [illegible] Mary L. Marsh, W. C. W. Nixon, A. D. C. Price, J. D. Ritchie, E. B. Rogers.

* Honours. § *Distinguished in pathology.*
† Distinguished in medicine. ‖ Distinguished in surgery.
‡ Distinguished in forensic medicine.

UNIVERSITY OF LIVERPOOL.

THE honorary degree of D.Sc. has been conferred upon Dr. George Barger, professor of chemistry in relation to medicine in the University of Edinburgh.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE following have been admitted Fellows of the Faculty: Robert Grieve Hutchison, M.B., Ch.B., and James Sharpe, M.B., Ch.B., D.P.H.

Medical News.

SIR CHARLES MARTIN will deliver his second and third Croonian Lectures before the Royal College of Physicians of London, at 5 p.m., on June 17th and 19th. His subject is the thermal adjustment of man to external conditions, more particularly those pertaining to warm countries. The first lecture was on June 12th.

THE annual general meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on June 25th, at 8 p.m., for the election of officers and to receive the report of the honorary secretaries and the financial statement. An ordinary meeting of the society will follow, when Professor J. S. Haldane, F.R.S., will read a paper on carbon monoxide poisoning, which will be followed by a discussion.

A MEETING of the Biochemical Society will be held in the Department of Biochemistry, Oxford, to-day (Saturday, June 14th), at 2.30 p.m., when papers will be read and demonstrations given.

THE annual meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded will be held in the Sandlebridge Institution, Alderley Edge, on Monday, June 23rd, at 3.15 p.m. The Lord Mayor of Manchester will preside, and will be supported by Miss Dendy, M.A., president, Sir Lewis Beard, and members of the governing body. The Thomasson and Sam Gamble day school will be open for inspection.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that the following lectures suitable for candidates for the M.R.C.P. examination will be given by Dr. O. L. V. de Wesselow at the Medical Society of London, 11, Chandos Street, Cavendish Square, at 8.30 p.m.: June 17th, "Hypotension and renal disease," and June 20th, "Diabetic and other acidoses." The fee for each lecture is 10s. 6d., payable at the lecture hall. On June 17th, at 2 p.m., Dr. E. U. Williams will give a clinical demonstration in the *x*-ray department of the Bolingbroke Hospital, Wandsworth Common, and on June 18th, at 11 a.m., Mr. G. H. Howells will demonstrate on ear, nose, and throat cases at the East London Hospital for Children, Shadwell. Both of these demonstrations are open to the medical profession, without fee or ticket. Three courses begin on June 16th, each of two weeks' duration: An intensive course in medicine and surgery at the North-East London Post-Graduate College (Prince of Wales's Hospital), Tottenham; the daily sessions will be from 10.30 a.m. to 5.30 p.m., and instruction will cover work in all departments; fee £5 5s., or £3 3s. for either week. A course in gynaecology at the Chelsea Hospital occupying some mornings and some afternoons; fee £5 5s. An afternoon course in diseases of the skin at the Blackfriars Hospital; fee £1 1s. From June 30th until July 5th there will be an all-day course in proctology at St. Mark's Hospital; fee £3 3s. Detailed syllabuses of all the courses can be obtained on application to the secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course of cancer and its treatment will be held at the University of Strasbourg from July 16th to 26th. Particulars may be obtained from Dr Gunsett, Directeur du Centre Anticancéreux, Hôpital Civil à Strasbourg.

SIR ANDREW BALFOUR, director of the London School of Hygiene and Tropical Medicine, will formally open the new research milk laboratories of the United Dairies, Ltd., at Scrubbs Lane, Willesden, on Monday, June 16th, at 1 p.m.

MISS BALSILLIE, who in March last was appointed principal matron in the service of the London County Council, has since intimated that she does not wish to take up the appointment, but to remain as matron of the Park Hospital, Hither Green. The Council has therefore appointed Miss Nellie Butler, matron of the Southern Hospital, Dartford, to the position.

COMMEMORATION DAY at Livingstone College, Leyton, was held on June 5th. A large number were present at this annual gathering in the grounds, including Sir George Makins, Dr. J. H. Cook, Dr. H. White, and many other representatives of missionary organizations and friends. The chair was taken by the Right Rev. Bishop Ward, president of the British Mission Board of the Moravian Church, who spoke of the personal knowledge he had of conditions in other lands, and of the mission hospitals he had visited in foreign fields. The Rev. R. E. Scott, of the Lebombo Mission, Portuguese East Africa, told of some of his experiences in the mission field, and testified to the practical worth of the training given at the college. Miss E. May Pateman, of the London Missionary Society, Gilbert Islands, said that the knowledge she had gained at Livingstone College had been of incalculable value to herself and others. Short statements as to finance and the general working of the college were made by the treasurer, Mr. R. L. Barclay, and the principal, Dr. Tom Jays.

AT a meeting of the committee of the Royal Eye Hospital, Eastbourne, on June 6th, Dr. Milner Moore, on his retirement from office, was presented with a portable wireless set, in appreciation of the services he had rendered that institution as honorary secretary for a period of seventeen years.

THE May issue of the *Bulletin of Hygiene* contains a review of recent literature on alcoholism—the third of an annual series—by Dr. J. D. Rolleston, dealing chiefly with its prevalence in various countries, with special reference to the cocktail habit and methyl alcohol drinking, the association of alcoholism with tuberculosis and mental disease, the decline of the use of alcohol in therapeutics, the diagnosis of alcoholism by colorimetric methods, and the recent drastic legislation in Soviet Russia for combating alcoholism. A bibliography of thirty-six references to the literature of nine different countries is appended.

THE fund being raised for the Birmingham Hospital Centre scheme reached the sum of £477,997 on June 6th. This amount included the £100,000 which Mr. Harry Vincent, president of the Birmingham and Midland Hospital for Diseases of the Nervous System, promised on condition that £350,000 was offered by the date mentioned.

THE challenge cup presented three years ago to the Metropolitan Counties Branch, to be awarded to the best all-round athlete who is a student at one of the London medical schools, was competed for at the United Hospitals annual sports, when Mr. Cramer, of the London Hospital, Mr. W. Hertzog, of Guy's Hospital, and Mr. Sandyford, of St. Thomas's Hospital, each won two events. These three gentlemen, therefore, will hold the cup jointly for the year.

IT has been agreed with the authorities of the London Hospital that the London County Council shall, as soon as the necessary arrangements can be made, undertake the responsibility for the conduct of the venereal diseases clinic at the hospital. An agreed amount will be paid by the Council for the use of the venereal diseases department, and the Council will take over such of the equipment in the clinic as is the property of the hospital at a valuation to be devised jointly by both parties. The clinic is to be open every weekday from 8 a.m. to 9 p.m., and also on Sundays.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF HEADACHE.

"SUBURBAN" asks for suggestions for treating a schoolmaster, aged 46, temperate in his habits, who suffers from headache after any kind of physical strain. The pain comes on a few seconds after the provoking cause. It does not last long, but if a further action is taken the pain becomes continuous and then persists for several hours. Mental work does not induce the headache. The patient has also a slight unsteadiness while walking, particularly if the head is turned upwards or sideways. Aspirin, in 10-grain doses, taken an hour or so before playing a game, will usually minimize the headache. The eyes have been examined and a slight defect corrected. The blood pressure is 140. There is a tendency to constipation, and a faint reduplication of the first mitral sound; the heart is otherwise normal. All the usual remedies have been tried, such as aperients, sedatives, alkalis, and anticatarrhal vaccines, with little more than temporary benefit.

PREVENTION OF SUNBURN.

DR. R. J. BROCKLEHURST (London, N.W.11) writes as follows in reply to Dr. I. B. McCann's query under the above heading: A liberal application of "pommade sechehaye" protects the skin efficiently against severe sunburn. It is a brown ointment, sold in tubes; the grotesque appearance of the face after its application is amply compensated by the subsequent absence of discomfort and disfigurement which are sustained by those who travel unprotected over the snow under the summer Alpine sun. It is obtainable everywhere in Switzerland, and is stocked in London by two or three dealers who sell Alpine equipment.

TREATMENT OF PRURITUS ANI.

DR. ROBERT E. LORD writes in reply to "Cerons's" inquiry (June 7th, p. 1089) as to the treatment of *pruritus ani*: Many years ago a patient, whom I still see frequently, suffered from intense *pruritus ani*, accompanied with a jelly-like discharge from just inside the anus. After many methods of treatment had been tried and discarded as useless, he found that he could always get relief from the application of the faradic current applied as strong as he could bear it, one pole being a metal rectal electrode and the other a flat electrode placed on the abdomen. He used this nightly for some months, and not only did the *pruritus gradually cease, but the jelly-like discharge* disappeared. There have been occasional relapses, but the same treatment has always succeeded in cutting them short, and he has had no return of symptoms for years.

DR. S. PENNY SNOOK (Weymouth) writes: I have found the occasional application of calomel ointment beneficial.

"G. P." writes: I have suffered from this complaint and am now (and have been for twenty years) cured, but I have *still* to continue the treatment, which is as follows: Wash the parts thoroughly with a sponge dripping with water (no soap); dry well, and apply a little of the following after each evacuation: zinc oxide in fine powder, pulv. amyli, equal parts; glycerinum q.s. Rub down to a soft paste. All greasy applications should be avoided.

INCOME TAX.

Professional Use of Residence.

"H. T." uses one room of his residence entirely and two rooms partly for professional purposes. The inspector of taxes agrees to the deduction of one-third of the rent, rates, etc., as applicable to the professional use, but will not allow more. Is this the usual proportion? The rateable value of the house is £34.

*** So much depends on the precise circumstances that it is difficult to advise specifically. If the three rooms in question are the best rooms on the ground floor they would account for considerably more than one-third of the total rental value, but the "waiting room" is, we gather from the total rental value, probably in fairly general private use. On the whole, while the proportion seems to us on the low side, we do not think it is entirely unreasonable, and "H. T." is not likely to obtain any substantial increase.

LETTERS, NOTES, ETC.

AORTIC ANEURYSM SIMULATING ASTHMA.

DR. F. WILLIAM COCK (Ashford) writes: The case of aortic aneurysm simulating asthma described by Dr. L. G. Hill (June 7th, p. 1048) is particularly interesting to me, as during a rearranging of the materials I collected for the account of the introduction of anaesthesia by Robert Liston I came across the notes of his necropsy made by Wm. Cadge in December, 1847. Dr. Hill's description is almost word for word that of Mr. Cadge. Liston, however, had a longer time for the disease to prove fatal—possibly a year, for after a very copious haemorrhage he survived for several months. He, too, had considerable asthma at the end. The small apertures from the aorta into the trachea were plugged with old ante-mortem fibrinous material. At that time (twenty years ago) I made many inquiries as to whether the specimen had been preserved, but no success followed, although I tried University College, the College of Surgeons, Edinburgh, and the Norwich Hospital, where Cadge's specimens are preserved. Sir William Osler particularly was interested because of the somewhat uncommon nature of the case. The condition was stated to be the after-effects of a blow on the sternum from the boom of his (Liston's) yacht.

SPONTANEOUS SURGICAL EMPHYSEMA.

DR. G. W. DANDO (Southsea) writes: In the *Journal* of August 29th, 1925 (p. 402), I reported a case of spontaneous surgical emphysema following the confinement of a young primipara; this closely corresponded with the cases described by Dr. F. Bedo Hobbs on May 24th (p. 950). My case occurred in the Crayford Nursing Home, Kent. The labour was a somewhat prolonged one, but the emphysema cleared up in a few days. I was unable at the time to find any reference to the condition in my textbooks.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 46, 47, 48, 51, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 49 and 50.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 267.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

533. The Lymphatic Reaction and Glandular Fever.

W. STEPP and H. WENDT (*Dent. med. Woch.*, April 18th, 1930, p. 645) review our present knowledge of cases variously described as lymphatic reaction, infective mononucleosis, and glandular fever. In adults the important clinical symptoms are tonsillitis, which may occur at the beginning or during the course of the illness; general enlargement of the lymphatic glands and of the spleen; fever, often high and remittent; and the characteristic blood picture with its increase of white cells usually to 10 or 20 thousand, 50 to 90 per cent. of which are lymphocytes. Some of the mononuclear cells are two or three times the normal size, and may have reniform nuclei; they give the normal staining reactions of lymphocytes, however. There may be an acute onset with all the appearances of severe illness, and the disease is often diagnosed as influenza at the commencement. Enlargement of the lymphatic glands and tonsillitis are occasionally absent throughout, as shown by two of the illustrative cases recorded by the authors. Organs such as the liver and kidneys are rarely involved, giving rise to jaundice and haematuria. The glandular fever of children (described by Pfeiffer in 1889) is held to be the same disease, since the same symptoms can occur both in children and in adults, and both types have been noted in the same epidemic. Diagnosis is often simple if the existence of the disease is borne in mind, but lymphatic leukaemia may be confused with it. Against the latter disease are the absence of anaemia and haemorrhagic diathesis. The general condition is worse in leukaemia; a sudden onset of the disease, and the later diminution in the size of the glands, are in favour of glandular fever. The total white count and percentage of lymphocytes, on the other hand, are not always helpful in diagnosis. The course of glandular fever is always benign, no undoubted case terminating fatally, or progressing into lymphatic leukaemia, having yet been established. The illness lasts for some weeks, after which the white count only gradually returns to normal. The origin of glandular fever is not yet known. Some authors have held that it is a constitutional abnormality, the lymphocytosis being a response to infection peculiar to certain individuals; this is rendered unlikely, however, as the patients respond normally to test injections of foreign proteins; moreover, small epidemics have been reported, suggesting a specific infective factor.

531. Extra-articular Forms of Rheumatism.

H. GRENET (*Presse Méd.*, March 12th, 1930, p. 353) notes that as far back as the time of Trousseau, the occurrence of visceral lesions was attributed to rheumatic disease, in the absence of any articular manifestations. Trousseau, however, gave few instances, and the tendency in medical literature has been to regard such lesions as rarities. Grenet records several examples of these lesions in his own practice, and places them in the following groups. (1) Pure infection forms; these may simulate typhoid fever, and be associated with enlargement of the spleen. Two cases are quoted, one of which was first mistaken for typhoid and the second for tuberculosis; both responded to salicylate treatment. A third case was that of a child who had typical rheumatic nodules without any arthropathy whatever. (2) The attenuated infection form; in such cases a history of previous acute rheumatism might be elicited. There was often slight fever, with pallor of the skin and mucous membranes. Severe cardiac lesions resulted from such cases being missed. (3) The pure visceral form; four varieties are mentioned, the first being cardiac lesions appearing with no previous warning of the nature of arthropathy. The pleuro-pulmonary variety, which was described by the older writers as associated with arthropathy, does occur in its absence. The oesophageal variety, associated with dysphagia, was previously described in association with arthropathy; it was not encountered by the author until he met with a case where mediastinitis and pericarditis, with displacement and constriction of the oesophagus, occurred without any joint lesions. The patient responded well to salicylates. Grenet recognizes a pseudo-surgical form; although it is generally taught that serous effusions due to rheumatism never go on to suppuration, he mentions a case where a pleural effusion (associated with endocarditis and pericardial inflammation) was followed by the aspiration of purulent material, which was sterile on culture. Blood cultures being also negative, salicylates were given, with the result that the whole condition cleared up without any surgical intervention. Certain cases coming under this heading may simulate acute abdominal conditions, such as appendicitis. The author emphasizes the importance of considering the possibility of rheumatism in all obscure febrile conditions; it is also pointed out that a careful inquiry into the previous existence of fleeting joint swellings and pains should never be omitted.

535. Pulmonary Atelectasis complicating Bronchial Asthma.

J. A. CLARKE, *jun.* (*Arch. Int. Med.*, April, 1930, p. 624), states that the occurrence of massive pulmonary collapse in typical bronchial asthma, independently of operative procedures, has been reported by Berkhard, by Kaufchorn and Ellis, and by Sante. He now records two additional cases, in one of which the condition was diagnosed by routine *x*-ray examination, and in the other only at the necropsy. Both patients showed the same symptoms as are noted in post-operative cases. In the patient with the favourable outcome the recovery was complete. The high incidence of allergy in subjects with post-operative atelectasis and the occurrence of atelectasis in asthmatic patients on whom surgical procedures have not been performed suggest that there is an allergic factor in post-operative atelectasis. Surgeons recognize two types of atelectasis, the fulminating and the latent. The fulminating symptomatology is possibly an allergic reaction to the bronchial secretion retained in the collapsed lung and absorbed with the air, similar to the reaction usually termed "bronchial asthma." The absence of the typical asthmatic rales over the uncollapsed lobes of the lungs is one point distinguishing this from the ordinary less severe paroxysms of asthma. Small areas of collapsed alveoli have been found after death in cases of true bronchial asthma; these are not uncommon, and may explain some of the severe paroxysms. It seems possible that lobar collapse might result from the coalescing of several such areas until the whole lobe would be involved without any obstruction in the larger bronchi. Acute obstructive emphysema should not be forgotten when such areas are found.

Surgery.

536. Chronic Duodenal Stenosis.

ACCORDING to R. APPELMANS, F. VAN GOIDSENHOVEN, and J. BOINE (*Rev. Belge des Sci. Méd.*, January, 1930, p. 1), chronic duodenal stenoses are relatively frequent and of various causation, four main groups being defined. In the first, the most important, the stenosis is due to compression by the superior mesenteric artery, the duodenum being held as in a vice between the root of the mesentery and the artery in front, and the aorta and vena cava, lying on the vertebral column, behind; in the second the middle colic artery is the constricting agent; in the third the duodenum is stenosed by adhesions of peritonitis, which may be primary, but is usually secondary to some other lesion; in the fourth group the stenosis is caused by adjacent tumours. Other less frequent causes are duodenal ptosis, cicatrices of duodenal ulcers, and congenital anomalies of the duodenum and of the suspensory system of Treitz. The four main groups are fully described, and cases illustrative of each are recorded. The symptomatology varies with the cause of the stenosis; by clinical and radiological signs it is often possible to differentiate the various types. Generally speaking, these stenoses cause digestive and general disturbances due to the intoxication produced by the duodenal stasis. Radiologically they can be recognized by the appearance of a dilatation above the constriction; the contents stagnate in the dilated part and undergo violent mixing by the peristaltic movements. In occasional cases few digestive troubles occur, and signs of toxic poisoning, such as great emaciation, physical and psychical asthenia, and headaches, predominate. When general symptoms coexist with digestive ones, even of a slight character, the duodenum should always be *x*-rayed; and also, since these stenoses can be caused by anomalies of the colon, the latter should be carefully examined in all cases of duodenal dilatation with stasis. When perduodenitis exists with the stenosis the cause should always be sought for and treated; the most usual cause is a duodenal ulcer, and the next most frequent the appendix. Haemorrhages without any discernible ulceration of the gastro duodenal

mucosa, and duodenal or pyloric ulcers, are complications of an existing duodenal stenosis. Medical treatment, principally by diet and laxatives, is sometimes useful and should be tried, especially in slight cases. However, recourse usually has to be made to surgical intervention, the operation of choice being a duodeno-jejunostomy.

537. Congenital Dislocation of Hip.

C. H. JAEGER (*Surg., Gynecol. and Obstet.*, April, 1930, p. 757) stresses the importance of diagnosing congenital dislocation of the hip as early as possible in infancy, and describes a new method of treatment which is said to effect physiological restoration of the joint within three months, and which can be applied to infants as young as 3 or 4 months. By its use the necessity for anaesthesia, manipulation, open operation, and plaster is avoided. Diagnostic signs of importance in unilateral cases are habitual outward rotation and shortening of the limb, apparent widening of the pelvis due to fullness over the trochanter, abnormal mobility in rotation, noticeable differences in the inguinal and gluteal folds, and the confirmation obtained by *x*-ray examination. The method of treatment aims at a gradual replacement of the dislocated head in the acetabulum by means of a pressure pad over the trochanter, the leg being held in marked abduction in a long hip splint. Reliance is placed upon the rapid growth in infancy to assist in the formation of a socket, the main requisite for the deepening of which is the removal of the pressure of the femoral head upon its upper rim. Jaeger disagrees with the view that functional weight-bearing is necessary for the operating of such a deepening process; he claims that *x*-ray examinations show that the rim develops rapidly as soon as the trochanter pad has pushed the head down to the position which is to become the socket.

538. Ureteral Lithiasis.

K. LANGE (*Deut. Zeit. f. Chir.*, April, 1930, p. 1) remarks that new diagnostic methods have shown that some diseases formerly regarded as rare are relatively frequent. This particularly applies to ureteral lithiasis and carcinoma of the lung, as had been formerly shown by Moynihan to be the case with duodenal ulcer. Two forms of ureteral lithiasis are described—namely: (1) the renal type in which the calculus has originated in the kidney and has become lodged in the ureter, and (2) the ureteral type, consisting in primary disease of the ureter with secondary calculus formation. As the result of his observations on 35 cases of ureteral calculus for which operations were performed at the Zwickau Hospital in the period 1924–29, Lange comes to the conclusion that the ureteral type is not so very uncommon, since 6 of the series were probably examples of the kind, and that its diagnosis is possible, while the prognosis is more favourable than that of the renal type owing to the possibility of already existing complications connected with the latter. Formerly about half the cases of the ureteral type were mistaken for appendicitis, but this error can be avoided by repeated examination of the urine, *x*-ray examinations, and cystoscopies. Early operation is particularly indicated in the ureteral type of calculus.

Therapeutics.

539. Prophylaxis of Measles with the Serum of Convalescents.

O. BANG (*Nordisk Medicinsk Tidskrift*, March 8th, 1930, p. 146) records the experience of the Blegdam Hospital in Copenhagen in the period 1926–28, during which the serum of convalescents from measles was given to 163 patients as a prophylactic measure. After the withdrawal of some of these cases as unsuitable for a comparative study, there remained 152 who were given intramuscular injections of serum; 4 of them developed more or less normal measles, and 8 an attenuated form of measles. Many of the patients were discharged from the hospital before the date at which it could be definitely claimed that they had escaped measles, but as many as 93 of those who did not develop measles were kept under observation for at least thirty days. In 122 cases escaping infection the observation period was at least fourteen days. The serum used was taken from the seventh to the tenth day after the temperature of the convalescent had become normal, and was prepared by the State Serum Institute. The dose for infants up to 1 year was 5 c.cm., for children from 1 to 3 years old it was 10 c.cm., and over the age of 3 it was 15 c.cm. The injection was given in every case on the first day of the appearance of a rash in a case of measles—that is, it was given on the second, third, or at most the fourth day of the incubation period. No ill effects from the serum were observed apart from a temperature of 100.5° to 101° on the day after the injection in 2 cases. Trying to ascertain why the serum failed to abort measles in 12 cases, the author noted that all the 4 patients in whom the serum failed completely to establish even temporary immunity were already very debilitated; many of the failures were in cases of whooping-cough. Thus, among 22 cases of diphtheria there was only one failure, and among 59 children admitted to hospital for a mixed assortment of ailments there was again only one failure, but among the 26 cases of whooping-cough there were as many as six failures, and among the 45 cases of scarlatina there were four failures. As the supply of the serum of convalescents is liable to be limited, it is necessary to decide which are the age groups to be given preferential treatment. The first year of life is the most dangerous: among all the deaths from measles in Denmark in the period 1922–27 there were 398 in the first year, 292 in the second year, 105 in the third year, 41 in the fourth year, and an average of only 6 in each of the years from the fifth to the tenth. The comparatively great number of deaths in the first year cannot be traced to a great number of infections, for their number was only 5,513—a mortality of 7.2 per cent. In the age period 1–5 years there were as many as 57,579 infections, with 479 deaths—a mortality of only 0.83 per cent. In the age period 5–15 years there were 73,157 infections, with 107 deaths—a mortality of only 0.15 per cent. With regard to the immunity acquired from the mother by the newborn infant, it is noteworthy that in the period under review there were only 6 deaths from measles in the first month of life, whereas there were 26 deaths between the second and third month, and 356 between the fourth and the twelfth month. The serum of convalescents may therefore be economized at the expense of the newborn, but only when it is established that their mothers have had measles.

540. Anti-asthmatic Drugs.

THOUGH observations on asthmatic subjects and their reactions to drugs after the development of symptoms have frequently been made, there is no record of similar observations immediately preceding, during the development and course of, or during recovery from, an attack subsequent to the administration of a broncho-dilating drug. O. W. BARLOW and J. F. FRYE (*Arch. Int. Med.*, April, 1930, p. 538) present such a study of an asthmatic case, in which uniform typical attacks could be produced by exercise (air hunger). In the patient no foci of infection could be detected, and the physical examination was negative, except for the observation of a slightly deflected nasal septum. The type of asthma was complex; it was primarily allergic, since a certain kind of dust invariably precipitated an attack, but it was also partly reflex, because the presence of an irritant in the air passages, and air hunger as a result of exercise, invariably produced typical asthmatic attacks. These symptomatic conditions differed in no respect from the usual allergic responses; they persisted for at least eight hours after development, and were promptly relieved by adrenaline. The criteria used for ascertaining the presence and the course of the asthmatic attacks were the respiratory movements and volume, and the degree of emphysema present; the respiratory and circulatory changes noted are described. The anti-asthmatic efficiency of adrenaline, ephedrine, and atropine was tested in this case, and their use during the induced attacks of asthma, as well as their routine employment over a three-year period, showed that their efficiency from greatest to least was in the order named. Adrenaline was the most potent, being effective in all attacks; ephedrine was most effective in relieving mild attacks or as a preventive; while atropine was unsatisfactory for either acute or mild attacks. The surgical correction of the deflected nasal septum did not significantly influence either the number or the severity of the allergic or reflex attacks during the year following operation.

541. Serum Treatment of Post-vaccinal Encephalitis.

J. HEKMAN (*Med. Welt*, February 22nd, 1930, p. 247) records in detail three cases, in children aged 6, 5, and 11 years, of encephalitis which developed from ten to twelve days after primary vaccination, and was cured by intravenous injections of the serum of the father or mother, who had been successfully vaccinated at the same time but without bad effects. Hekman adds that five more cases were cured in the same way in the Bergweg hospital, and that he had heard of good results obtained by other practitioners with this method. The number of injections was one, two, and five respectively in the three cases, the dose being 10 c.cm. He also describes a case of post-vaccinal encephalitis in a boy, aged 4, which ended fatally in spite of seven intravenous injections of serum. In this case, however, the serum of the parents was not available, and the serum of the donor in one of the successful cases was used.

Anaesthetics.

542. Rectal Anaesthesia with Avertin.

A. SPIEGEL (*Amer. Journ. of Surg.*, January, 1930, p. 97) describes the administration of and results obtained from avertin used as a rectal anaesthetic. Avertin, chemically known as tribromethylalcohol, was produced through the reduction of bromal by means of yeast. It is a white crystalline substance which is sensitive to light and air; if heated above 40° C. hydrobromic acid is split off and dibromacetaldehyde, which is a severe irritant to the mucous membrane of the colon, is formed. Avertin is absorbed by the colon more rapidly than water, and in case of ill effect it would be of little use to withdraw the remaining fluid since the greater part of the avertin would already have been absorbed; the safety of the drug is dependent upon the relatively large margin between narcotic and lethal doses, the latter being twice the dose required for anaesthesia, which varies from 100 to 185 mg. per kilogram. Pre-operative treatment consists of an enema the night before with 5 grains of veronal to ensure sleep; half an hour before the operation, morphine sulphate (¼ grain) and atropine sulphate (1/150 grain) may be given. During administration the patient lies on the left side and the fluid is slowly injected into the rectum with a large syringe, the tube being pushed upwards into the sigmoid. About five minutes after the avertin has been given the patient falls asleep and is completely anaesthetized after fifteen or twenty minutes. The operation can safely last for two or three hours. There were no deaths from avertin in 100 cases reported, and post-operative vomiting in only 6 cases.

543. General Anaesthesia by Intravenous Alcohol Injections.

M. G. MARIN (*Arch. Internat. de Laryngol.*, February, 1930, p. 244) describes his attempts to find an anaesthetic agent less toxic than those usually employed, and claims that the intravenous administration of ethyl alcohol is much superior to the anaesthetic methods at present in use. Ethyl alcohol is said to be 137 times less toxic than chloroform, and is in addition a cardiac tonic. The advantages of the intravenous route of administration are the absence of preliminary syncope which is produced reflexly by the irritation of inhalation anaesthetics and the elimination of post-anaesthetic pulmonary complications. Moreover, in operations on the head and neck the operation field is left entirely to the surgeon. The author claims that there is more relaxation and less movement of the abdomen in operations in that region than with any other anaesthetic agent. The preparation used is a mixture of 90 per cent. ethyl alcohol with a 25 per cent. hypertonic solution of glucose; 2 to 3 c.cm. of alcohol per kilogram of body weight are required, and the total dose is dissolved in 60 c.cm. of the glucose solution. Marin adds that this dose, which was found satisfactory in Mexico, is possibly rather high for the anaesthetization of European patients.

544. R. PALMA (*Rif. Med.*, April 7th, 1930, p. 515) has experimented with the Marin method of producing general anaesthesia by the intravenous injection of ethyl alcohol in a 25 per cent. glucose solution. This is injected alternately with a certain quantity of isotonic glucose solution; 3 to 4 c.cm. of alcohol for each kilogram of body weight is required to produce a general anaesthesia in five to fifteen minutes, and lasts one to one and a half hours. According to Marin it can be administered to patients suffering from Bright's disease, diabetes, or cardiac disorders. General anaesthesia was produced by this method on nineteen dogs subjected to various operations. The quantity of alcohol administered varied for each individual dog, thus showing that for alcohol the same rule applies as with other narcotics. The previous injection of 1 to 2 cg. of morphine did not influence the anaesthesia in any way. Breathing, at first deep, becomes gradually more superficial and remains so during the whole time. The blood pressure is not altered at first, but as soon as the anaesthetic dose is reached the pressure falls abruptly and remains low during narcosis. This is in accordance with the known physiopathological actions of alcohol and glucose, and is contrary to the findings of Marin and Constantin, who have recorded an initial rise and subsequent normal pressure. Four out of nine cases presented transitory renal lesions, such as albuminuria with the appearance of granular and blood casts, and in two cases there was retarded elimination of indigo-carmine injected intramuscularly. These lesions are, however, described as being transitory and not due to alcohol. One day after the operation anatomical lesions, such as renal congestion and haemorrhages, were found, especially in the medulla. A notable complication was a venous thrombosis at the site of the injection; this was the cause of death of two of the animals. The thrombosis is certainly due to alcohol, and its dilution with glucose does not eliminate this possibility. The author concludes that this method of anaesthesia is not devoid of danger, and may perhaps give rise to embolism, pulmonary congestion, renal lesions, and excessive lowering of the blood pressure.

545. Spinal Anaesthesia with Gravity Solutions.

WHILE the controllability in spinal anaesthesia of Pitkin's novocain solution (spinocain), which is lighter than spinal fluid, has been ably demonstrated, it became apparent that the usefulness of this form of anaesthesia would be enhanced if a solution heavier than spinal fluid was also available. F. T. ROMBERGER (*Amer. Journ. of Surg.*, April, 1930, p. 773) describes his trial of such a solution, which he terms "novocain solution heavy"; it contains 40 per cent. of novocain as compared with the 10 per cent. of spinocain. The author points out that with spinocain the patient's head must be kept down in order to avoid blocking the cervical nerve roots and medulla—that is, the Trendelenburg position must be assumed; with the heavy solution the head must be kept up, Fowler's position being adopted. The anterior roots of the spinal nerves control voluntary motion and the superficial and deep reflexes; hence, when these are affected by the anaesthetic, muscular paralysis and relaxation (motor block) occur. The posterior roots are sensory, and therefore, when these are affected, all sensations of pain, touch, and temperature are lost (sensory block). By means of diagrams Romberger shows that with spinocain the sensory roots are paralysed as high as the second dorsal vertebra and the motor roots at the sixth cervical; while with novocain solution heavy the sensory roots are paralysed to the seventh cervical vertebra and the motor roots to the third dorsal only. These are the highest levels of spinal anaesthesia which are warranted for any type of surgery. The heavy solution is particularly indicated in those patients who are elderly, or who are suffering from cardiac disease or asthma, and in whom respiratory embarrassment must be avoided; it is also particularly useful when it is desired to limit the anaesthesia to the perineum. To obtain uniformly optimum results in the block, corresponding percentages of novocain must be injected into the subarachnoid space. The anaesthesia obtained by 100 to 120 mg. of novocain lasts for three-quarters to one and a half hours, with an average of one hour. Larger amounts up to 400 to 600 mg. can be used, but the employment of such doses requires a perfection of technique, judgement, and experience. The great benefit of giving ephedrine in large doses is emphasized, and also that, to get any response, this drug must be given before the block is established—that is, before splanchnic paralysis has occurred. The necessity of a strict aseptic technique is also emphasized.

Obstetrics and Gynaecology.

546. Puerperal Scarlet Fever.

J. DELORME (*Thèse de Paris*, 1930, No. 44), who records six illustrative cases, states that lying-in women may contract true scarlet fever which may properly be called puerperal, with certain peculiar features, such as absence of sore throat associated with little or no uterine infection. On the other hand, lying-in women may develop puerperal scarlatiniform erythema, which must not be confounded with true scarlet fever in spite of an undoubted clinical relationship. Apart from cases in which there is an obvious spread of infection from the sick to the healthy, the diagnosis between true scarlet fever and puerperal scarlatiniform erythema can only be made by the Schultz-Charlton test. Contrary to the opinion generally held, Delorme holds that the newborn child is not absolutely immune to scarlatinal infection, and that therefore it should be isolated lest infection take place.

547. Retention of Dead Ectopic Foetus.

R. BERNARD (*Presse Méd.*, February 19th, 1930, p. 252) states that although there are cases on record in which a dead ectopic foetus has been retained for an indefinite period without untoward results, yet, once the diagnosis has been made, surgical intervention becomes obligatory. If the death occurred some time previously the operation should be immediate; but if the death is recent then regression of the placental vascularization should be awaited; Brindeau estimated the period of choice as between four and six weeks after death. The present author quotes Courtois as defining three methods of treatment: (1) marsupialization; (2) extirpation of the sac and placenta without drainage;

and (3) removal of the foetus followed by closure of the abdominal wall without drainage. Marsupialization has the advantages of a good immediate prognosis and is easy to perform, but the risk of secondary haemorrhage and of septicaemia gives a mortality ranging from 13 to 40 per cent., according to different authors. Extirpation of the sac and placenta, although the most rational method in the author's opinion, is to be avoided. In support of his view he cites a case of his own in which the actual operation was easily and rapidly performed. At the end of the operation the patient was pulseless, although respirations continued for a time, the picture being one of toxic shock; in spite of vigorous anti-shock treatment death ensued from "toxic shock," "anaphylactic shock," or toxaemia. From a study of the literature the author concludes that such terminations to the operation are not uncommon; Courtois thinks they occur in 4 per cent. The method of choice in these cases appears to be to remove the foetus and, leaving the placenta and sac *in situ*, to close the abdominal wall. The placental circulation is thus gradually arrested as absorption proceeds.

548. Glucose-Insulin Treatment of Hyperemesis Gravidarum.

P. CAFFIER (*Zentralbl. f. Gynäk.*, March 22nd, 1930, p. 723) describes twenty cases of moderately severe hyperemesis gravidarum subjected to combined glucose and insulin treatment. On the first day the stomach and bowel were washed out, and on the second day (after rectal lavage) in the morning and afternoon the patient was given by drop-by-drop rectal injection 30 to 50 c.cm. of 10 per cent. glucose solution. Each injection was followed by 10 to 15 units of insulin given subcutaneously, and up to this time, with the exception of fragments of ice, both food and drink were rigorously withheld. If vomiting had not ceased this treatment was repeated on the third and other days. Twenty-four hours after the cessation of vomiting sips of cool sweetened cocoa were given, replaced, if nausea was induced, by intravenous sugar injections. During this stage, and the subsequent one of light dieting, insulin injections were continued twice daily in sequence to oral administrations of sugar—two or three grams to one unit. Insulin injections were given until discharge from hospital, the preceding sugar feeds being omitted when ordinary diet was reached. Of twenty patients, two left hospital relieved before the completion of treatment, seven were completely cured, four had recurrences eventually cured by the same means, two improved but aborted, and there were five failures. Of these, one patient aborted, but in the remainder cure was eventually attained by dietetic and psychotherapeutic measures, after insulin-glucose medication had been suspended on account of icterus or hypoglycaemic shock (two cases each). The treatment is only suitable for hospital trial, and its chief drawback is the risk of inducing hypoglycaemic shock. Other observers also have reported a fairly high incidence of abortions after the treatment, and insulin has been found to diminish fertility in animals.

549. Pruritus Vulvae.

ACCORDING to H. POUEY (*La Gynécol.*, December, 1929, p. 711) the most common sites of pruritis vulvae are the clitoris, labia, vestibule, and perianal region; it may extend to the genito-crural folds, pubis, or vagina, may become localized in a small area (constant in the same patient) of the genital zone, and may be associated or alternate with nasal or plantar pruritus. In vulval pruritus the general causes of pruritus in other regions are usually absent, but in the great majority of cases the patient suffers in addition from morbid nervous conditions, such as hypochondria, neurasthenia, hysteria, epilepsy, vaginismus, frigidity, or crises of anal sphincteralgia. The usual duration of the crisis is from three to five minutes, and the usual incidence is several times a day, but more frequently during the night. In at least one-third of the cases vulval lesions may be noted, of which the most frequent are eczema, leucoplakia, and furunculosis; in nearly one-third of cases a chronic cervicitis with leucorrhoea is present, and in both groups cure of the associated disease is in many cases followed by disappearance of the pruritus. It may occur regularly before, during, or after the menses, and may be noted only during pregnancy. The pruritus of diabetics may disappear after a dietetic reduction which is not sufficient to abolish glycosuria. About 5 per cent. of sufferers from pruritus are sexually frigid. Treatment must be preceded by an exhaustive physical examination; the cure of cystocele, prolapse, cervicitis, haemorrhoids, fistula, and glycosuria will frequently cure pruritus vulvae. Local bathing with 2 per cent. silver nitrate solution is recommended, followed by the application of red or yellow precipitate ointment. For nocturnal pruritus local application may be made before bedtime of half an ounce of lukewarm water containing one gram each of antipyrin, laudanum, and potassium bromide. Anaesthetic injections into the bladder are used for hospital patients. For vaginal irrigation, ensol, 5 per cent. carbolic acid, 5 per cent. copper sulphate solution, or mercuric chloride (1 in 10,000) may be used. The scope, in refractory cases, of *x*-ray and radium treatment, and of wide or localized vulvectomy, is illustrated by case-histories.

Pathology.

550. Influence of Hepatic Innervation on Alimentary Hyperglycaemia.

F. CONTI (*Il Policlinico*, Sez. Med., April 1st, 1930, p. 183), with a view to determine in the case of alimentary hyperglycaemia the action of a nervous stimulus produced by a diet of carbohydrates and the glycogenolytic function of the liver, has conducted experiments on dogs by isolating this organ from its nerve connexions, thereby studying the variations of alimentary hyperglycaemia. This condition appeared to be more moderate after such an operation, suggesting the existence of a stimulus exercised by the exogenous glucose on the hepatic glycogenesis. Other complementary investigations proved that such a phenomenon was not due to variations of the intrahepatic circulatory regimen, but that there exists an entero-hepatic reflex stimulated by the introduced carbohydrates. To demonstrate this reflex, produced through the vegetative nervous system, attempts were made to paralyse simultaneously its two sections with products of pharmaco-dynamic action, but they failed. The lowering of the glycaemic curve was not obtained by a direct injection of glucose into the portal system, excluding thus the hypothesis that the phenomenon is due to circulatory disturbances following isolation of the nerves. The author concludes that in hyperglycaemia there exists a component due to glucose secreted from the liver by nervous stimulation, and another component probably represented by a part of the glucose absorbed by the intestines.

551. The Protective Power of B.C.G.

P. MAURIAC and E. AUBERTIN (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, January 20th, 1930, p. 57) inoculated with virulent tubercle bacilli three dogs which had been previously vaccinated with B.C.G. Subsequently two of them were subjected to chronic phosphorus and thyroxin poisoning. Neither of these animals, nor the control, exhibited any tuberculous lesion when killed seven months after inoculation with tubercle bacilli. Similar results were obtained in three heifers, killed seven months after the intravenous injection of virulent bovine tubercle bacilli. Experimental intoxication by thyroxin or phosphorus did not modify the immunity produced by B.C.G. in dogs and cattle. The authors also inoculated guinea-pigs and rabbits with B.C.G., and subsequently with virulent tubercle bacilli; these animals were then submitted to chronic poisoning by phosphorus, thyroxin, and uranium nitrate. The immunity attained under these conditions appeared uncertain; some of the animals when killed exhibited tuberculous lesions.

552. Br. abortus Infection in Latvia.

E. DARSIN (*Zentralbl. f. Bakt.*, February 20th, 1930, p. 457) between September, 1928, and June, 1929, examined 1,100 human serums sent in to the Hygienic Institute at Riga for agglutinins to *Br. abortus*. As agglutinating antigen living suspensions of several strains of this organism were used, washed off agar slope cultures three to five days old. The serums examined were sent in either for a Wassermann or a Widal test. Agglutination to a titre of 1 in 100 or over was regarded as a positive reaction to *Br. abortus*. Of the 1,100 serums, 18, or 1.6 per cent., reacted positively. This percentage is considerably less than that recorded by Kristensen in Denmark. Clinically the chief symptoms were irregular fever of a low type, obstinate headache, and joint pains, particularly of the lower extremities, and general laxity. Fever of the typically undulant type was only seen on one or two occasions. Two of the patients, both of whom had apparently been infected from aborting cows, had been ill for three years or more. Attempts to isolate *Br. abortus* from these two patients proved unsuccessful, but the cultures were made in Veillon tubes and were apparently not incubated in 5 to 10 per cent. CO_2. From one patient, who had a suppurative lesion in connexion with a metatarsal bone, a strain of *B. proteus* was isolated, which was agglutinated by the patient's serum to about 1 in 200. This strain was likewise agglutinated by certain other serums that were positive to *Br. abortus*, but not by *abortus*-negative serums. The meaning of this coagglutination was not fully elucidated.

PNEUMONIA

Excellent results have been obtained in the treatment of Pneumonia with

OPTOCHIN BASE

(Ethylhydrocupreine Alkaloid)

OPTOCHIN BASE (Howards) is a synthetic derivative of QUININE with a definite bactericidal action to all types of pneumococcus.

Given orally in tablets or powder, **OPTOCHIN BASE (Howards)** is well adapted for use by the General Practitioner and is of great value in Pneumonia of children and adults.

In 2-grain tablets and in powder.

RHEUMATISM, GOUT, NEURITIS, SCIATICA, LUMBAGO, etc.

Reports from eminent medical men show that

AGOTAN (HOWARDS)

BRAND

(Phenyl Cinchoninic Acid B.P.C.)

is remarkably successful in the treatment of Rheumatoid conditions due to excess of Uric Acid. Owing to the powerful elimination of Uric Acid **from the blood,** under the influence of Agotan, the deposition in joints, etc., is prevented or reduced, thus avoiding or **quickly removing** local manifestations.

In 7½-grain tablets, in powder, and in tubes for local application.

Literature will be sent on request to the Manufacturers

Local Anæsthesia in Surgical Practice

SEPTIC ARTHRITIS.

Typical Case.

Mrs. E. C. H., aged 45 years.

Diagnosis: Septic arthritis of left hip.

Operation: Arthrotomy and drainage.

Anaesthesia: Local infiltration, 180 c.c. of 0.5 per cent. Novocain-Adrenaline solution.

Operation: Patient was given an injection of scopolamine 1/200 gr. and pantapon 1/3 gr. two hours before the operation and one hour before. Infiltration was made along the lateral aspect of the thigh and a longitudinal incision was made down to the abscess cavity. 500 c.c. of creamy pus escaped. The finger was introduced and the hip-joint was explored. A long curved forceps was introduced, and after infiltrating the gluteal region an incision was made down to the forceps. Dakin's tubes were introduced through the counter opening, and passive motion was carried out daily. The patient was discharged with a movable hip.

—EXTRACT from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified *patients* of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 55, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms etc., apply to the Medical Superintendent*

THE TREATMENT OF GOUT

PISTANY

RADIO-ACTIVE MUD PACKS

PISTANY SPA REPRESENTATION,

135, Regent St., London, W.1. Tel. Gerrard 9506

Pistany (Czechoslovakia) offers the most effective treatment for the cure of gout.

Special provision is made for the diet of gouty patients in the hotels.

In mild cases a few weeks suffice to relieve the condition but the need for prolonged intermittent treatment often makes a course with Pistany Mud Cubes or Compresses at home, under the patient's own doctor's supervision indispensable for a complete cure.

The method of application is safe and inexpensive for Pistany's sulphur Mud is inert and sterile of mineral content and keeps indefinitely.

Send for interesting Medical and Tourist literature.

UNIVERSITY OF LONDON.

EXTERNAL EXAMINERSHIPS, 1931.

The Senate announce the following vacant External Examinerships for all Examinations above Matriculation for the year 1931. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included.

For the First Examination for Medical Degrees.
CHEMISTRY.

For the Second Examination for Medical Degrees.
PHARMACOLOGY.

For Final and Higher Examinations for Medical Degrees.
MEDICINE. SURGERY.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it.

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable, on or before Monday, July 7th, 1930. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

University of London, South Kensington, S.W.7. EDWIN DELLER, Principal.

June, 1930.

POST-GRADUATE MIDWIFERY.

Qualified Medical Women are admitted to **The Mothers' Hospital of the Salvation Army, Lower Clapton Road, E.5** for practical fortnightly Courses in Midwifery. These include delivery of normal cases, attendances at all abnormal cases, operations, ward rounds of visiting staff, V.D. clinics, and ante-natal clinics. For further particulars, fees, etc., apply to EDGAR DIBDEN, the Secretary.

Doctors attending Post-Graduate Courses in London, requiring Comfortable ACCOMMODATION with good cooking at moderate terms. Ideal position, facing Hyde Park. Send for Tariff.—Park Gate Hotel (over Lancaster Gate Tube Station), Bayswater Road, London, W.2. Telephone: Paddington 3421.

WEST AFRICAN MEDICAL STAFF.

Vacancies at present exist for MEDICAL OFFICERS in the WEST AFRICAN MEDICAL STAFF.

Qualifications. Candidates must be British subjects of European parentage and under 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

Salary. £660 per annum, rising by annual increments of £30 per annum to £720 per annum, and then, on confirmation, £720 per annum, rising by annual increments of £40 to £960 per annum, together with a seniority allowance (payable only in West Africa) at the rate of £72 per annum. After three years' service on £960, the salary may be raised to the scale of £1,000 per annum, rising by annual increments of £50 to £1,150 per annum, together with a seniority allowance at the rate of £100 per annum.

Quarters. Free quarters are provided or an allowance is given in lieu.

Outfit Allowance. An outfit allowance of £60 is granted on first appointment.

Passages. Free first-class passages are provided for the officer only both on first appointment and when proceeding on or returning from leave. A married officer will, in certain circumstances, be granted half the cost of his wife's passages to and from West Africa.

Terms of Appointment. The appointments are pensionable, subject to a probationary period of three years in the first instance.

Tour of Service. The normal tour of service in West Africa is approximately 18 months, though vacation leave may be granted by the Governor after 12 months, and is followed by leave at the rate of one week for each completed month of residential service, plus the time necessarily spent in the voyages to and from England.

Course of Instruction in Tropical Medicine. Selected candidates will normally be required to attend a course of instruction in Tropical Medicine and Hygiene before proceeding overseas.

Duties. Though Medical Officers are appointed in the first instance for general service, there are good opportunities for work in special branches of medicine and surgery and for research.

Further particulars and forms of application may be obtained, on application in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Onderstepoort, South Africa.

THREE RESEARCH FELLOWSHIPS.

Applications are invited for Three Research Fellowships tenable at the ONDERSTEPOORT VETERINARY RESEARCH LABORATORY, PRETORIA. These Fellowships have been established by the Empire Marketing Board in conjunction with the Government of the Union of South Africa.

Candidates will be required in each case to furnish proof that they are familiar with particular aspects of research, namely:

(1) *First Fellowship*, methods of tissue culture and work with filterable viruses;
(2) *Second Fellowship*, bacteriological work and the physiology of animals, especially ruminants;
(3) *Third Fellowship*, methods of extracting toxic substances from plants and determining the nature of such substances.

Selection will be made by a Committee consisting of the President of the Royal Society, the High Commissioner for the Union of South Africa in London, the Chairman of the Research Grants Committee of the Empire Marketing Board, and the Director of the Imperial Bureau of Animal Health.

The Fellowships will be tenable for a period of three years with the possibility of renewal for a further period of two years. Remuneration will normally be at a rate not less than £800 and not more than £1,000 per annum, but special consideration may be given to candidates whose qualifications and other circumstances warrant a higher rate.

Each successful candidate will be provided with a free passage for himself and his family from his place of residence to Pretoria. Duties should commence as early as possible.

During the tenure of the Fellowship the holder will be responsible to the Director of the Onderstepoort Laboratory.

Applications should be addressed to the Secretary, Empire Marketing Board, 2, Queen Anne's Gate Buildings, London, S.W.1 (cables "Empmart, London"), and should be received not later than September 1st, 1930.

Applications should be accompanied by six typed copies each of three testimonials and references to any published work.

University College Hospital,

Gower Street, W.C.1.

Applications are invited for the post of HONORARY ANAESTHETIST to University College Hospital, and should be forwarded to the Secretary before noon on Friday, June 27th.

Countess of Dufferin's Fund.

WOMEN'S MEDICAL SERVICE FOR INDIA.

Medical Women are invited to apply for the following posts, which must be taken up by the end of October:

(1) MEDICAL WOMAN for General Service. Emoluments: Rs. 550 per mensem, rising; furnished quarters; provident fund; passage and outfit allowance.
(2) MEDICAL WOMAN, with special experience in Maternity and Child Welfare and administration in Public Health work. Emoluments: Rs. 750 per mensem, rising; furnished quarters; provident fund; passage and outfit allowance.

Applications, on special form to be obtained from undersigned, with copies of three recent testimonials, should be returned by Friday, July 11th, to Hon. Secretary, United Kingdom Branch Dufferin Fund, c/o Major-General Sir LEONARD ROGERS, India Office, Whitehall, S.W.1.

June 10th, 1930.

Walsall General Hospital,

WALSALL.

The Committee invite applications from men for the post of CASUALTY HOUSE SURGEON. Salary £120 per annum.

Candidates, who must be registered under the Medical Acts, must produce three recent testimonials.

The appointment will be for six months.

The Hospital contains 100 beds and is equipped in all Special Departments.

Applications, stating age, qualifications, and nationality, must be received by the undersigned not later than first post Tuesday, June 17th.

WALTER FRANCOMBE, Secretary.

Lincoln County Hospital.

Wanted, a JUNIOR HOUSE SURGEON, male, unmarried. Salary at the rate of £150 per annum, rising to £200 per annum at the conclusion of six months' approved service. Board, residence, and washing will also be provided.

Every candidate for the appointment must be registered under the Medical Acts.

Applications, stating age and other particulars, with copies of testimonials (not more than three), are to be sent to the undersigned, from whom further particulars may be obtained.

Lincoln. ARTHUR MOORE,
June 10th, 1930. Secretary-Supt.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

The Surrey County Council invites applications from registered male Medical Practitioners for the post of Assistant Medical Officer. Applicants must not be over 35 years of age, and must possess the Diploma of Public Health. The duties of the post include the Medical Inspection of School Children; work under the Maternity and Child Welfare and Tuberculosis Acts, and Venereal Diseases Regulations; and such other Public Health duties as may be allocated to him. The person appointed will be required to devote his whole time to the service of the County Council and reside in the County. The salary will be £600 a year, rising by annual increments of £20 to a maximum of £700, together with travelling expenses in accordance with the Council's scale.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form which can be obtained together with further particulars from the County Medical Officer, County Hall, Kingston-upon-Thames, to whom the completed forms should be returned not later than Saturday, June 28th. All communications must be endorsed "Assistant Medical Officer."

Any form of canvassing is strictly forbidden, and will disqualify.

County Hall, DUDLEY AUKLAND,
Kingston-upon-Thames. Clerk of the
June 7th, 1930. Council.

Chesterfield and North Derbyshire Royal Hospital.

(190 Surgical and Medical Beds.)

CASUALTY OFFICER.

Applications are invited from fully qualified men for the above post. The appointment is for six months. The Casualty Officer is next in seniority to the R.S.O., and acts for him in his absence.

Candidates must have held previous Hospital appointments.

Salary at the rate of £200 per annum, with board, apartments, and laundry. Duties include those of House Surgeon to the Ear, Nose, and Throat Department.

Applications, stating age, together with copies of three recent testimonials, should be sent to the undersigned not later than Thursday, 12th instant.

G. SUNNUCK,
June 2nd, 1930. Supt. & Secretary.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts, and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank	Basic Pay	Overseas Pay	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£70	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
„ 18 „ „ „	450
„ 19 „ „ „	460
„ 20 „ „ „	500
„ 21 „ „ „	540
„ 22 „ „ „	580
„ 23 „ „ „	620
„ 24 „ „ „	660
„ 25 „ „ „	700
„ 26 „ „ „	730
„ 27 „ „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office in July, and the selected candidates will be required to join a course of instruction commencing early in August, 1930. Applications should be submitted as soon as possible.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.
Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

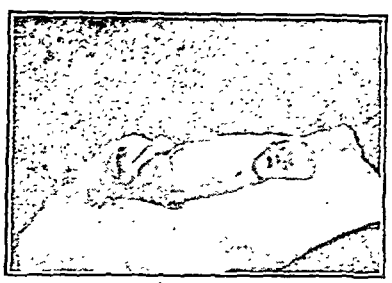
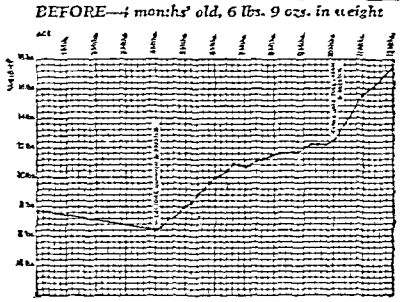
NATURALLY RICH

IN VITAMIN "D"



A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs. 9 ozs.) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia. The infant was put on to LACIDAC (Separated) with a small quantity of BRESTOL and immediately made steady progress.



At 6 months he had gained 3 lbs. 7 ozs. and by the end of another 4 months his weight was 12 lbs. 6 ozs., and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol.

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby.

His Doctor considers him a '*Resurrection.*'

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight

Progress chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight

Write for literature and clinical samples of Lacidac and Brestol.

Cow & Gate Milk Food

Support Home Agriculture—THIS is ALL BRITISH MILK.

COW & GATE LTD. GUILDFORD, SURREY

The Pre-eminent Vitamin Food.

'BYNOTONE'

Contains essentially—bone marrow, yeast extract, hæmoglobin, liver fat and a proportion of irradiated ergosterol.

It is thus a concentrated nutrient, rich in the vitamins A, B and D and other elements which, often deficient in the ordinary everyday diet, are of vital importance to nutrition.

"Bynotone" is the ideal accessory food during the ages of active growth and adolescence, the periods of expectant and nursing motherhood and the stage of convalescence after acute disease.

Literature and clinical trial sample will be sent post free on request.

The "Allenburys"

"CHARKAOLIN" GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

Reliable Pituitary Products

'PITUITRIN'—the first posterior extract to be placed at the disposal of the medical profession—was introduced in 1908 and has always been in the front rank of its class.

Parke, Davis & Co.'s experience in this connection is unique and enables them to offer preparations that are unsurpassed for uniformity of strength, reliability of action and freedom from excess proteins.

Parke, Davis & Co.'s research workers showed in 1927 that there are at least two active principles in 'Pituitrin.' These are now available in 'Pitocin' (the oxytocic principle), and 'Pitressin' (the pressor and anti-diuretic principle).

'PITUITRIN' is standardized to contain 10 International units of oxytocic activity per c.c.; it is standardized, also, to contain 10 pressor units per c.c.

'PITRESSIN' is standardized to contain 20 pressor units per c.c. It is indicated for controlling the polyuria of diabetes insipidus, for the relief of post-operative paralytic flatulence, maintaining blood-pressure in pneumonia and diphtheria, and for the prevention of post-operative shock and collapse.

'PITOCIN' is standardized to contain 10 International units of oxytocic activity per c.c.; it is indicated as a stimulant to the uterus in labour when the uterine contractions are inadequate, especially when an increase in blood-pressure is undesirable, as in eclampsia.

LABORATORIES: HOUNSLOW, MIDDLESEX.

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—**It is effective.** It supplies the physiologically active calcium ion.

2.—**It shows distinct superiority** in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—**It enables physicians to adequately meet the requirements of any given case.**

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—**It is completely sufficient in itself as a therapeutic agent.**

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

THE ENDOCRINES IN GENERAL MEDICINE

By W. LANGDON BROWN, M.A., M.D., F.R.C.P. (Physician to St. Bartholomew's Hospital). 7s. 6d. net.

"The combination of early physiological work, clinical experience, and wide reading has enabled Dr. W. Langdon Brown to write a clear and philosophical handbook full of suggestive ideas on this difficult subject. Attractive from its potentialities and therefore open to rash speculation in the armchair, the therapeutic use of endocrine preparations is much in need of such an authoritative and well-considered opinion."—*Extract* BRITISH MEDICAL JOURNAL.

BACTERIAL VACCINES AND THEIR POSITION IN THERAPEUTICS

By LEONARD S. DUDGEON, C.M.G., C.B.E., F.R.C.P. *Demy 8vo. 96 pages.* 7s. 6d. net.

"This book should prove most helpful to all those who are interested in the subject."—BRITISH MEDICAL JOURNAL.
"We can confidently recommend this handy and up-to-date volume on vaccine therapy."—MEDICAL TIMES.

MODERN VIEWS ON THE TOXAEMIAS OF PREGNANCY

By O. L. V. de WESSELOW, M.B., F.R.C.P., and J. M. WYATT, M.B., F.R.C.P.

Demy 8vo. 108 pages. 7s. 6d. net.

"The authors have succeeded in collecting and presenting in a readable form the more important facts gained from recent scientific research, and this book will certainly afford some guidance in the management of difficult cases."—BRITISH MEDICAL JOURNAL.

HEART DISEASE IN CHILDHOOD

By H. B. RUSSELL, M.D., M.R.C.P., and C. K. J. HAMILTON, B.M., M.R.C.P.

Demy 8vo. 104 pages. 7s. 6d. net.

"The authors have treated their subject in a lucid and most able manner, discussing the problems with which every practitioner has to contend, and explaining methods of diagnosis and treatment."—MEDICAL TIMES.
"This book will be warmly welcomed, dealing as it does with a subject which is engaging so much attention at the present time."—NURSING TIMES.

MODERN DIAGNOSIS AND TREATMENT OF SYPHILIS CHANCROID AND GONORRHOEA

By L. W. HARRISON, D.S.O., M.B., Ch.B., M.R.C.P.E. Demy 8vo. 176 pages. 10s. 6d. net.

"This is a handy volume written by an admitted authority on venereal disease. It deals with the clinical diagnosis, prevention, and treatment of syphilis, including a useful chapter on the management of syphilis; the general principles of treatment of gonorrhoea are clearly presented and modern methods of treatment lucidly described."—BRITISH MEDICAL JOURNAL.
"It gives a lucid and concise account of syphilis, chancroid and gonorrhoea in all their manifestations, and with the sections on diagnosis and treatment no fault can be found. To the busy practitioner who cannot overtake the modern literature it should be very useful."—LANCET.

DISEASES OF THE

NOSE, THROAT & EAR

For Practitioners and Students.

Edited by A. LOGAN TURNER, M.D., LL.D., F.R.C.S.E.,

Cons. Surgeon, Ear and Throat Dept., Royal Infirmary, Edin.

WITH THE COLLABORATION OF

J. S. FRASER, M.B., F.R.C.S.E., J. D. LITHGOW, M.B., F.R.C.S.E., W. T. GARDINER, M.C., M.B., F.R.C.S.E., G. EWART MARTIN, M.B., F.R.C.S.E., and DOUGLAS GUTHRIE, M.D., F.R.C.S.E.

"There is no other book which includes laryngology and otology with such success."—BRIT. MED. JOUR.
"May confidently be recommended for the use of students and practitioners."—LANCET.
"Will prove of the greatest value."—JL. OF LARYNGOL. & OTOL.

JUST PUBLISHED. SIXTH EDITION. Fully Revised. Crown 8vo. 684 pp. With 163 Illustrations, some of which are coloured. 17s. 6d. *net; postage* 6d.

SYNOPSIS OF

SURGERY

By ERNEST W. HEY GROVES, M.S., M.D., B.Sc.Lond., F.R.C.S.Eng.,

Professor of Surgery, Univ. of Bristol; Surgeon, Bristol General Hospital; Member of the Court of Examiners, Royal College of Surgeons, England; Examiner in Surgery, Universities of London, Liverpool, Leeds, Manchester and Sheffield, and Nat. Univ. of Ireland.

"Complete in its range of subjects . . . among the best of its kind; the author is to be congratulated on its readableness, its lucidity and its fullness—notable qualities."—BRIT. MED. JOUR.

"This synopsis of surgery has had a wide sale, which has necessitated the issue of frequent editions, and it deserves thoroughly all the success it has attained."—LANCET.

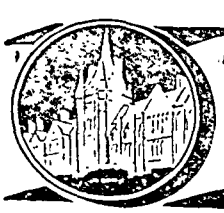
"The Rose Corset-Belt"



for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

The U.G.B. MEDICAL BOTTLE Service

Photograph of actual package of Cork-mouth bottles with cover removed.

THE U.G.B. Washed and Sterilized medical bottle service—introduced early in 1929—has proved to be an unqualified success, so much so that we were recently compelled to increase the capacity of our washing and sterilizing plant.

The screw cap service is in particular demand, and owing to the preference of users for a cap in a neutral colour, we have now standardized in fitting the bottle with an attractive RUSTLESS WHITE ENAMELLED CAP.

Photograph of actual package of Screw-cap bottles with cover removed.

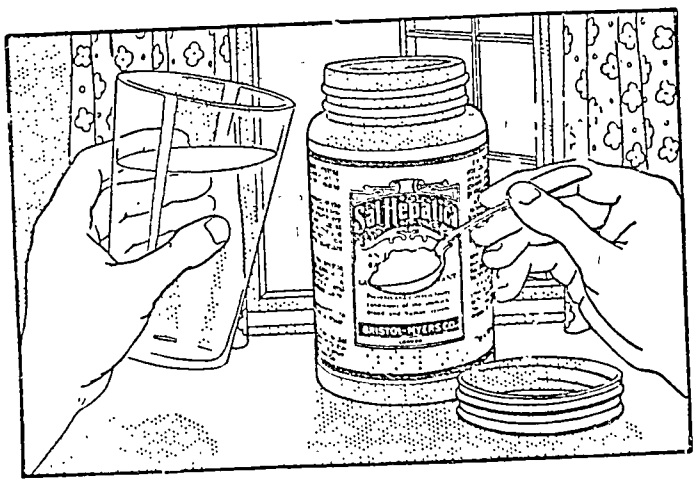
MICKLEFIELD IRRADIATED MILK

Treating the Cow.

By this process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.



(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

Full particulars appeared in an article in the LANCET, January 18th, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every weekday in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

A prompt, painless eliminant and anti-acid.

One or two drachms of Sal Hepatica induces quick, painless and complete evacuation, which eliminates all toxic substances, reduces the blood pressure and renders the blood and urine alkaline. ¶ The toxic amino-acids present in the system which result in diabetes, rheumatism, gout, sciatica, lumbago, neuritis and all other disorders associated with acidosis, can be eliminated daily by the exhibition of Sal Hepatica. ¶ Sal Hepatica is non-habit-forming.

BACILLUS COLI BACILLURIA & URINARY INFECTIONS

CONDITIONS dependent upon infection of the urinary tract by *B coli* are by no means uncommon, and present varying degrees of severity, from serious suppurative lesions of the kidney to mild bacilluria of little importance.

The mechanism of infection by *B. coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B. coli* are common in urinary infections in the male).

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed, and those already located in the urinary tract may be attacked by a urinary antiseptic By the combined administration of Kerol, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B. coli* is placed on a rational basis, and many cases are cured by this line of treatment when they fail to yield to urotropin alone.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W. Borchardt (*Deut. med. Woch.*, March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow, others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the red rib-marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1.4 mg. per cent. The result was similar but more striking, the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years.

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

MORNING SICKNESS

A PHYSICIAN writes:—"That the best method of preventing Morning Sickness, or in difficult cases of considerably relieving the nausea of Morning Sickness, is to prescribe a cup of hot Humanised Trufood, taken the first thing in the morning and at night. In cases of poor appetite Humanised Trufood should be taken at other meals throughout the day. This elegant preparation is so palatable, nutritious and easily digested that it is readily retained by the most delicate stomach. Not only does it afford strengthening nourishment to the expectant mother, but it also provides the correct food for the baby at all times when carrying. Humanised Trufood practically resembles natural breast milk and is the only scientifically correct bottle-food for babies. It gives the best nourishment, too, in all cases of indigestion and stomach trouble."

Sample and literature promptly sent on request.

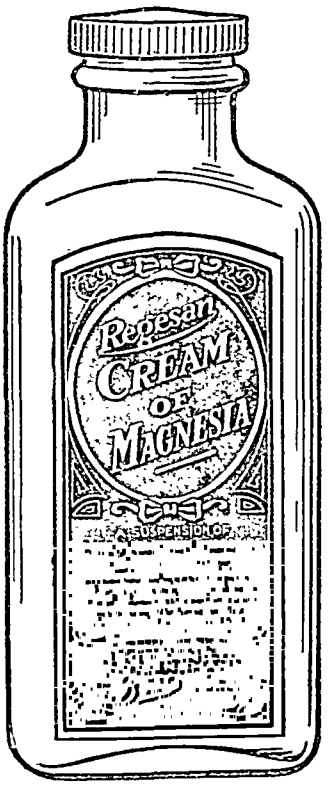
The Medical Profession when prescribing Liquor Carbonis Detergens SHOULD ADD THE WORD



Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Regesan

CREAM OF MAGNESIA

A pure, finely divided Magnesium Hydroxide ($Mg(OH)_2$) suspended in water. A simple antacid and valuable laxative. Digestive troubles and gastric conditions indicating the necessity of a corrective of this type quickly respond to treatment with Regesan Cream of Magnesia.
It does not gripe nor cause discomfort, and is mild in action.

Price 1/3 per bottle.

THESE ESSENCES RESTORE VITALITY

AND STIMULATE THE APPETITE

RECENT investigation proves that 99 *out of every* 100 *doctors interviewed* recommend Brand's Essences in cases where the need for an easily assimilated food is imperative!

Absorption by the digestive system is so rapid that, in states of extreme exhaustion, they restore vitality almost immediately. And during convalescence, when the very thought of ordinary food is repugnant, these Essences help to stimulate the appetite and create a desire for the solid diet which is so vital to recovery.

For Brand's Essences consist entirely of the pure juices of the finest fresh meat—conserved in their natural form—a delicious jelly. Nothing is added which could prevent easy assimilation—no flavouring, no gelatine, no colouring.

Brand's Essences are obtainable at chemists and stores throughout the world in tins and glasses. A professional card will bring you samples of the Essences immediately. Write Dept. F7, Brand & Company Limited, Mayfair Works, Vauxhall, London, s.w.8.

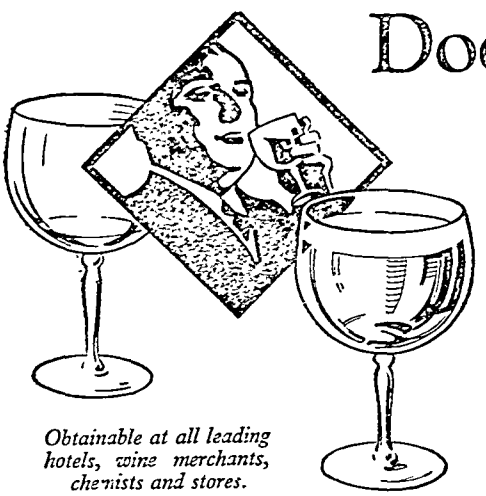
LIVER EXTRACT B.D.H.

One of the outstanding scientific discoveries of the last few years is the fact that pernicious anaemia may be cured by the administration of liver. Experience has shown, however, that only liver preparations of known activity are efficacious. (*Lancet*, Nov. 30, 1929, p. 1145.)

In the treatment of pernicious anaemia—and other anaemias which resemble the pernicious type in that they appear to be associated with megaloblastic hyperplasia of the bone marrow—a reliable liver product is described as *"a certain remedy."* (*Lancet*, March 15, 1930, p. 586.)



Clinical trials made with Liver Extract B.D.H. show that this extract is highly effective in inducing blood regeneration.

Liver Extract B.D.H. is made by a process tested and found efficient by the Medical Research Council; it is a palatable product of known potency and hence is prescribed by a large number of physicians.

a new antiseptic
QUINANIL
ANIL - QUINOLINE 48 S

THIS important new antiseptic is the result of research carried out by a group of workers at the University of Leeds under the auspices of the Medical Research Council. It has been subjected to thorough clinical trials in the General Infirmary, Leeds. Boots Pure Drug Co. Ltd. have been supplying QUINANIL for these clinical trials, and the results were reported in the *Lancet* of November 9th, 1929. Every batch of QUINANIL—BOOTS is submitted before issue to the University of Leeds for approval, and ample supplies are now available for the use of the Medical Profession. QUINANIL is usually employed in solution in normal saline, the strengths used varying from 0·005% (1:20,000) to 0·1% (1:1,000). *See Lancet of November 9th, 1929, p. 969.*

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7

Works: KING'S LANGLEY, HERTFORDSHIRE.

M275

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER Ltd., Manufacturing Chemists,
184, Queen's Gate. London, S.W.7.

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational advertising but by the constant recommendation of medical men and women. To-day it is universally used not only at home but throughout the world. Few foods have so enjoyed the approbation of the Medical Profession for over 40 years.

Benger's Food differs from all other foods in that it is especially prepared to adjust fresh cows' milk or cows' milk and water so as to suit the condition of any patient. While it is largely used as a routine treatment in all cases of disordered digestion the following comments, which have been recently made by Doctors, indicate some specific uses to which Benger's Food has been put.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

ANTIPHLOGISTINE

An Effective Antacid and Digestant

The Physician is constantly called upon to prescribe for digestive disturbances. In the treatment of such cases, BiSoDoL will be found a reliable preparation.

BiSoDoL is a balanced formula presenting in suitable proportions the bases Sodium and Magnesium, with Bismuth Subnitrate, Carica Papaya, Malt Diastase and Mentha Piperita.

BiSoDoL is agreeable to the Patient and no unpleasant symptoms follow its administration.

BiSoDoL is quickly effective. Beneficial results have been especially marked in cases of impaired digestion, and in the control of cyclic vomiting, and the morning sickness of pregnancy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

BiSoDoL Limited,
12, Chenies Street, London, W.C. 1.

HEWLETT'S ORIGINAL PREPARATIONS.

ANTISEPTIC CREAM

(Cremor Antisepticus)

(HEWLETT'S)

A delicate antiseptic emollient healing Cream, instantly relieving the itching and burning sensation of the skin in cutaneous diseases. Its healing and soothing properties are widely recognized in the treatment of Wounds.

Price, in Collapsible Tubes 18/- per doz., or 5, 10, 22, 40, and 90-oz. Jars, 5/6 per lb.

GARGAR. FORMALIN CO.

(HEWLETT'S)

A most economical, efficient, and pleasant gargle and mouth wash, containing Formalin, Glyc. Acid Carbolic, Tinct. Pyrethri, etc., suitably flavoured. It is highly concentrated, one fluid drachm being sufficient for an eight ounce bottle.

PRICE 5/6 PER LB.

"Please supply us with a two pound bottle of Gargarisma Formalin Co. We have tried a small quantity and find our patients like it."—L.D.S.Eng.

HORMONIGEN

(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the pluriglandular system, and in anæmia. In Amenorrhœa, Dysmenorrhœa, and at the Menopause, Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE: HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

TABLETS SODIO-CALCII LACTAS cum PARATHYROID

Each tablet contains 2½ grains Sodio-Calcium Lactate with Parathyroid 1/20 grain.

These tablets have been found most valuable in the treatment of Hæmorrhage in cases so frequently found in Sanatoria, Tuberculosis Clinics, etc., and in the treatment of Strumous Children unable to extract nourishment from their food. They may be given every two or three hours.

PRICE 3/- PER 100; 28/6 PER 1,000.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent. of Iodine, and is, therefore, stronger than the B.P. Ointment, whilst it does not harden or discolour the skin.

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc. Ung. Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis.

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

VERONIGEN

(Formerly known as MIST. VERONAL CO.)

(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, 10/6 PER LB.

TOWNS OF THE TIME OF JUSTINIAN AS REPRESENTED BY THE BYZANTINES.—Throughout the thousand years that Byzantium was the capital of the intellectual world, she gathered up, as it were, the elements of the older civilisations, developed and fused them with an inspiration of her own and presented the result to the world at the end of the Middle Ages. Byzantium educated the Slavs and the Arabs, the latter receiving instruction in medicine (a subject in which they later excelled), as well as the basis of their fine architecture. The representations of towns here reproduced are not very faithful ones. They would seem to be borrowed from the antique world. Nevertheless, they may be looked upon as typifying the evolution wrought by the Byzantines, particularly in their most enterprising period.

Observations
ON
SOME SKIN AFFECTIONS DUE TO YEAST-LIKE FUNGI.*

BY
J. M. H. MacLEOD, M.D., F.R.C.P.,
PHYSICIAN FOR DISEASES OF THE SKIN, CHARING CROSS HOSPITAL; HONORARY DIRECTOR OF THE PATHOLOGICAL DEPARTMENT OF ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

WITHIN recent years considerable advances have been made in the etiology of skin diseases by the discovery that certain "yeast-like" fungi, previously believed to be saprophytic and harmless in the skin, are pathogenic and responsible for various forms of dermatitis of which the causation has long been a matter of controversy. As these affections are commonly met with in general practice, and since on the recognition of their cause depends their rational and successful treatment, I have chosen them as the matter of this address. I propose to illustrate it by a series of lantern slides, which have been specially prepared from photographs of cases in my own practice or which have been kindly lent me by my colleagues, and from specimens and cultures made in the St. John's laboratory.

It is only within the last few years that the yeast-like fungi pathogenic in the skin have attracted much attention in this country, and most of the literature is American, French, or German. I do not propose to discuss the different mycotic findings in their chronological order, or to attempt to apportion the credit due to the various workers on the subject, but simply to describe in a general way the present position. At the same time, however, I should like to express our indebtedness to all the workers on the subject—to Gilchrist, Stokes, Ricketts, Ormsby, Shelmire, Weidman, Finnerud, and others in America, to Dubreuilh and Ravaut in France, to various workers in Germany and Austria, and to Castellani, Chalmers, and my colleague J. B. Dowling in this country.

As a preliminary it will be necessary to consider briefly the group known as the yeast-like fungi from their close relationship and morphological similarity to the yeast fungus (*Saccharomyces cerevisiae*). The fungi in question belong to the group of the "fungi imperfecti," and are of a lower order than the yeasts, in that reproduction takes place in the simplest manner by budding, without the formation of asci (receptacles containing spores). They consist of the Monilias, the Pityrosporon of Malassez, and, of a higher order and more nearly related to yeasts, the Blastomyces and Coccidioides. These fungi are members of the great botanical division of the Thallophyta, and have a vegetative part consisting of mycelium, made up of filaments or hyphae, usually septate, and a reproductive part consisting of spores which multiply by budding, or under certain conditions are developed from hyphae as lateral buds or conidia.

As early as 1889, when Tommasoli described six different yeasts which might occur in the epidermis, it was known that yeasts were common denizens of the skin, and to be found chiefly in moist intertriginous parts such as the axillae and genito-crural region. They seem to be especially common in the skin in tropical countries, and Castellani years ago observed a number of cases of yeast infections in Ceylon, to which he gave the name of intertrigo saccharomycetica.

There was no consensus of opinion, however, as to whether the yeasts were responsible for the intertrigo or simply existed in these regions as harmless saprophytes. Since then cases have been reported from time to time in which fungi believed to be yeasts and to be pathogenic have been isolated in intertriginous dermatitis. In the light of the study of monilia infections and further knowledge of the true yeasts it appears that in such cases the fungi are not saccharomyces, but monilias and other yeast-like fungi. It is now known that the yeast fungus itself is not pathogenic; when inoculated on the skin it produces no definite lesion, and men whose occupation entails constant handling of yeast, such as workers in breweries, are not specially subject to dermatitis, whilst baker's itch, once attributed to yeast, is now considered to be due to the hygroscopic action of the dough itself.

* Delivered before the Isle of Thanet Division of the British Medical Association.

MONILIAS.

The monilias belong to the family of the Oosporaceae. They reproduce themselves by free spores or conidia, and present budding forms on cultivation on artificial media. The spores are ovoid or rounded in shape, vary in size from 2μ to 6μ in diameter, and have a tendency to be arranged in chains, hence the name monilia, from *monile*, a necklace; the mycelium shows hyphae, which are usually long and septate. In culture the fungi are Gram-positive, liquefy gelatin, and ferment certain sugars such as glucose and maltose, with, in the case of glucose, the formation of gas and the emission of a characteristic odour. They grow readily on Sabouraud's maltose agar at 25° C. in from twenty-four to forty-eight hours; young cultures show round or ovoid yeast-like cells, and older cultures single or branched mycelial hyphae with lateral buds.

There are several varieties of monilia, certain of which are pathogenic, while others are only saprophytic. Morphologically they may be indistinguishable, but differences can be detected by means of biochemical tests based on their capacity of fermenting different sugars. The most familiar member of the group is the *Oidium albicans* of thrush, which it is now customary to designate the *Monilia albicans*. Other well-known pathogenic monilia are the *M. pinoyi* and *M. candida*.

The *M. albicans* is a slightly higher fungus than the others in that culturally it occasionally shows endospores, and certain mycologists have claimed it as an endomyces. The cultural distinctions between the *M. albicans* and the *M. pinoyi* on maltose agar are as follows: the *M. albicans* at 25° C. grows in twenty-four to forty-eight hours as a crinkled culture of a light yellowish-brown tint, while the *M. pinoyi* on the same medium and at the same temperature appears as pinhead-sized hemispherical colonies, which are smooth, shiny, and of a dirty beige tint, which is darker in the centre.

Mucous Membrane Lesions due to Monilia.

Monilias may produce lesions in the mucous membranes in the mouth, vagina, anus, and bronchi. It was in 1853 that Charles Robin gave the name of *Oidium albicans* to the fungus of thrush, and it was believed for long afterwards that this familiar clinical condition was due to a single fungus. It is now known that a number of different fungi may be responsible for it, not only monilias, but cryptococci, and possibly others.

In the mouth the fungi produce the well-known whitish or cream-coloured, wash-leather-like membranous patches, situated on the tongue and the inner surface of the cheeks, which on removal leave a raw red surface but no ulceration or bleeding. Not infrequently cracks appear on the tongue or at the commissures of the mouth, where they may be associated with maceration, desquamation, and crusting of the red portions of the lips, and with an erythemato-squamous dermatitis spreading for a quarter of an inch or more from the corners of the mouth, which is generally known as "perlèche," and was attributed until recently either to a streptococcal or staphylococcal infection.

In a case under my care, in a boy aged 10 years, with extensive thrush of the mouth and associated perlèche, *M. pinoyi* were found in scrapings of the scales at the angles of the mouth as well as in the buccal mucosa. In another case, in a girl aged 8 years, crusted, cracked patches were present at the angles of the mouth, at the nasal orifices, and on the eyelids, and from these lesions the *M. pinoyi* was isolated and cultivated.

In 1929 Finnerud reported an epidemic of perlèche in an orphanage near Chicago in which 100 cases occurred out of 1,250 children.

It appeared first as greyish-white thickenings on the mucous membrane side near the angles of the mouth and spread out on the neighbouring skin in the form of erythemato-scaly or crusted patches with one or more cracks. In certain of the cases perlèche-like lesions were also present at the nasal orifices, and in one or two instances scaly patches like seborrhoeic dermatitis were observed on the chin and cheeks. In 77 per cent. of the cases fungi of the monilia or cryptococcus type were isolated. It was believed that the infection in this epidemic had been spread by drinking-vessels, sucking pencils, the use of common towels, kissing, or possibly by the habit the children had of sharing fruit with each other and even biting the same apple.

In the vagina monilia infection may give rise to a membranous or purulent vaginitis suggesting gonorrhoea. It would seem to be specially prevalent in diabetics and in pregnant women. Cases of conjugal infection where a

husband has presumably contracted it from an infected wife have also been reported.

Monilia infection has been known to occur in the mucosa near the anal orifice in association with the presence of the fungus in the rectum and in the faeces, and to spread from there to the circum-anal skin; it may also occur in the urethra and glans penis.

Skin Lesions due to Monilia.

The lesions of the skin which may be caused by monilias are almost as multiform as those due to the fungi of ringworm. At the same time apparently identical lesions may be produced by different monilias, and it is just as impossible to predict the exact fungus responsible in monilia infections from the appearance of the clinical lesions as it is to foretell the precise microsporon or trichophyton which has caused a patch of ringworm. The cutaneous lesions due to pathogenic monilias may be widely distributed, certain parts, such as the intertriginous regions, being specially involved, or they may be localized in one or more situations as in perlèche or perionychia.

The disseminated type is met with most commonly in suckling infants, in whom the eruption may or may not be associated with buccal thrush. It is usually first seen around the anus, and spreads from there to the genito-crural fold and genitalia and down the thighs. In severe cases it may extend to the buttocks, abdomen, interdigital spaces of the hands and feet, and may even be met with on the palms, soles, and face. The initial lesion is either an erythemato-squamous macule, or a superficial vesicle or vesico-pustule, which on rupturing leaves a small denuded surface enclosed by a ring of undermined epidermis. These lesions increase peripherally to form confluent patches with an indefinite border of detached epidermis, beyond which are numerous isolated vesicles or inflamed scaly macules. In older patches the scaliness may so predominate that an appearance results which is indistinguishable clinically from ringworm. As a rule, however, the presence of the detached epidermal border enclosing a pinkish, somewhat moist central patch will serve to indicate the diagnosis.

In severe cases the fungus may be present in the alimentary tract and stools, and it is in such cases that there is a danger of general infection, which has been known to terminate fatally. Buccal moniliasis in sucklings may lead to infection of the nipples and breasts of the mother.

In the adult the intertriginous regions usually implicated in body ringworm—namely, the genito-crural region, axillae, beneath the breasts in stout women, and the interdigital folds—are the usual sites of infection. As in the infant, the eruption begins as minute papules or vesicles which eventually form a red scaly patch, irregular in outline, occasionally fissured, and bounded by an edge of detached epithelium, beyond which variously sized discrete lesions may extend for some distance. The presence and growth of the fungi in the skin causes itching, and certain cases of pruritus ani or vulvae are caused by it.

E. C. Smith, in an interesting paper on dermo-moniliasis among natives of West Africa, isolated monilias which he regarded as pathogenic in connexion with a desquamative dermatitis of the scrotum, psoriasis-like patches scattered over the trunk and limbs, and lesions of an impetiginous character covered with crusts. The fungus, believed to be *M. pinoyi*, was found microscopically in scrapings, in culture, and in histological sections about the hair follicles, but not in the hairs themselves.

There are various factors which predispose the skin to monilia infection by rendering it a suitable soil for the growth of the fungus. These are the moisture and warmth of the intertriginous regions; excessive sweating; the presence of glycosuria, sugar favouring the growth of the fungus; and maceration of the skin from wet dressings, or from immersion in continuous baths, such as those employed in Vienna as a routine treatment for certain cutaneous affections. In the continuous bath cases it is usually most marked about the hands, knees, and axillae, regions which are not continuously immersed, but for parts of the day are out of water and exposed to the air.

In the interdigital folds monilia infections are indistinguishable from ringworm, and may occur as a papular or vesicular eruption like dysidrosis, which spreads from the clefts to the neighbouring skin of the back of the hands or the dorsum of the foot, or it may appear as whitish patches of sodden skin, not infrequently fissured, to which type of lesion Fabry gave the name of "Erosio interdigitalis seu blastomycetica."

Another variety of monilia infection is perionychia, chiefly of the fingers, with a pad- or bolster-like swelling of the nail-walls, which on being squeezed emits a bead of pus on to the nail-plate, the result of the presence of minute abscesses on the undersurface of the nail-wall. This condition is painful and singularly intractable. It is most common in women, and seems to be especially prevalent in those whose occupation necessitates the handling of sugar, such as confectionery workers, pastrycooks, etc. In these industries various factors are combined which further the inoculation and growth of the fungus—for example, the heat of the workrooms, the moistness of the hands of the operators, the sugar, and the liability to abrasions from sugar granules or traumatism.

The nails themselves may be infected by monilia by spreading of the fungus from the nail-fold or the nail-bed. The appearance of the affected nails is similar to ringworm. In both the nail-plate becomes opaque, discoloured, irregular, ridged, and brittle, and may be raised up from the nail-bed by greyish-white keratotic masses. In certain cases the infection takes place from the mouth, and may persist indefinitely after the buccal thrush has been cured.

In a case of this kind which came under my observation a lady sought advice on account of an affection of the nails of the hand which had been present since childhood. The appearance of the nails suggested ringworm, but on microscopical and cultural examination the fungus found proved to be the *M. albicans*. All manner of treatment had been tried without success, and even on one occasion the nails were removed, but the affection recurred with their regrowth. There was a history of recurrent attacks of inflammatory perionychia, but at the time of examination the perionychia was quiescent. As it had been present in infancy it was regarded by the patient as a congenital defect. On questioning her it transpired that as a baby she had suffered from persistent buccal thrush, and there seemed little doubt that the infection had taken place at that time and continued ever since.

This case is interesting in that it shows that an apparently trivial action such as sucking the fingers in infancy may have a profound influence throughout life.

Pathogenicity of the Monilias.

Numerous inoculation experiments have proved that certain monilias are definitely pathogenic. By inoculation on normal skin of culture material from monilia lesions in the mouth or skin a vesico-pustular dermatitis can be produced, and from the roofs of the vesicles and from scrapings of the experimental lesions the fungus can be recovered, demonstrated microscopically, and successfully cultivated. Conclusive experiments of this kind have been done by various workers, including myself, both with the *M. albicans* and the *M. pinoyi*. As a rule the artificially produced lesions clear up rapidly under treatment or even become involuted spontaneously, but this does not invalidate the pathogenicity of the fungus, as the inoculated skin may have been uncongenial soil for its growth. The inoculations took best in the intertriginous situations, such as the anal fold and the interdigital spaces.

In the epidemic of perlèche described by Finnerud, lesions of a persistent type and indistinguishable from perlèche were produced in nine out of ten cases experimentally inoculated from pure culture of monilia, and from them the organism was recovered and cultivated.

So far as I am aware no successful experiments have been carried out in connexion with inflammatory perionychia due to monilia in man, but Guggenheim claims to have infected the claws of a guinea-pig by the inoculation of a culture from moniliasis of the human nail. Animal experiments have also been done with the fungi in mice, rats, rabbits, and guinea-pigs, by local inoculation on the shaved skin and by subcutaneous, intraperitoneal, and intravenous injection. In this way inflammatory lesions have been produced in the skin of a papulo-vesicular or scaly type, while intravenous injection of a culture of *M. albicans* in mice has proved fatal, and intramuscular inoculation in a guinea-pig has given rise to local abscesses.

In short, both human and animal experiments have proved that two at least of the monilias are pathogenic and conform to Koch's postulates.

Diagnosis of Moniliasis.

The diagnosis of cutaneous moniliasis from the clinical appearance of the lesions is as a rule impossible, but the presence of lesions in intertriginous parts associated with buccal thrush should naturally suggest a common origin, and the peculiar type of perionychia with its bolster-like nail-wall, beads of pus, and discoloured, opaque nail-plate should point to a monilia infection. In every instance the diagnosis should be confirmed by a microscopical examination. With this object scrapings should be made of the cutaneous patches or of the affected nails, and examined microscopically, either in potash solution or after staining by Gram or gentian violet, and the microscopical findings confirmed by cultivation on maltose agar.

Treatment of Moniliasis.

The treatment of moniliasis depends on the situation affected.

In buccal cases the mouth should be cleansed with a 2 per cent. aqueous solution of borax and potassium chlorate, and the membranous parts of the tongue and cheek painted subsequently with a 1 per cent. aqueous solution of gentian violet. The use of artificial teats should be discontinued as they are liable to harbour infection.

Lesions in the intertriginous parts should be treated with potassium permanganate baths followed by the application of a 2 per cent. benzoic and salicylic ointment, or of a 2 to 5 per cent. solution of gentian violet in 15 per cent. spirit.

In the interdigital spaces the papulo-vesicular type may be cured by the use of Whitfield's benzoic and salicylic ointment or by the application of 1 per cent. chrysarobin ointment, but in the resistant type with white sodden fissured skin more drastic treatment is necessary, and it may even be necessary to resort to curettage and the application of 5 to 10 per cent. solution of silver nitrate.

In perlèche from monilia the application of 6 to 10 per cent. solution of silver nitrate or the gentian violet solution should effect a cure.

In suppurative perionychia the hands should be immersed in warm saline solution for half an hour, dried, and then painted with 5 per cent. solution of silver nitrate or 10 per cent. solution of iodine, which should be pushed in below the nail-walls as far as possible with a soft camel-hair brush. This treatment should be repeated at intervals of two or three days until a cure is effected.

In monilia of the nails the treatment is as unsatisfactory as in ringworm. An attempt may be made to cure them by soaking the affected fingers in warm saline solution, scraping the nail-plate as thin as possible, and dressing either with the following iodine solution (iodine 1, potassium iodide 2, water 1,000) or with Fehling's solution. It may even be necessary to extirpate the affected nails, and treat the nail-bed freely with gentian violet solution till regrowth of the nail takes place.

THE PITYROSPORON.

The second yeast-like fungus to which I wish to refer is the pityrosporon.

This organism was first recognized by Malassez in 1874, and was named after him the "spore of Malassez." It was designated subsequently by Unna, on account of its shape, the "flask-shaped bacillus" or *B. asciformis*, by Hodara the "balloon bacillus," and by Sabouraud the "bottle bacillus." As the organism is one of the yeast-like fungi of the family of the Cryptococcaceae (Kützing), and not a bacillus, it is inadvisable to perpetuate these synonyms, however descriptive of its morphology they may be, and to adhere to the title of "spore of Malassez," or, as it produces a scaly dermatitis, the pityrosporon. Like the monilias it is of a lower order than the yeasts, and shows no reproductive asci on cultivation; it is believed to be closely allied to the *Microsporon furfur* of pityriasis versicolor.

Morphology.—The morphology of the fungus can be studied in extempore preparations of scales and scrapings in liquor potassae, and in stained preparations of scales and cultures. It is Gram-positive, and stains readily with gentian violet, methylene blue, and Giemsa. Its spores are polymorphic, and vary considerably in shape and size. Their usual form is that of a gourd or flask with a large spherical portion surmounted by a small, rounded process or bud, but they may be hour-glass shaped, or, more rarely, ovoid, round, or sausage-shaped. In size they average from 2μ to 4μ in their long diameter. They may be arranged singly or in groups or chains varying in number up to twenty or more. In preparations from the skin and cultures from solid media no mycelium can be detected, but in fluid media mycelium is found in abundance in the form of delicate non-septate hyphae with clubbed extremities and lateral buds. It is distinguished from monilia in that the spores are polymorphic, instead of being ovoid or lemon-shaped; they average in size about 3μ in diameter, while the monilia spore averages about 4μ, and on cultivation the pityrosporon shows no mycelium on solid media, but abundant mycelium with thin, delicate hyphae in fluid media, while monilia shows mycelium with thick hyphae in solid media and no mycelium in fluid media.

Cultivation.—Great difficulties have been met with in the cultivation of this organism. As early as 1908 Mr. W. G. Garner, pathological assistant in the laboratory of St. John's Hospital, succeeded in growing it at 25° C. on acid glycerin agar, Sabouraud's maltose agar, and peptone broth with the addition of 1 per cent. oleic acid and 1 per cent. glucose, by scraping scales off the scalp with a sterilized knife into a sterile watch-glass and planting them on the media. On solid media it grew in twenty-four to forty-eight hours as a white, glistening, smooth culture, which readily assumed a yellowish or fawn tint. On oleic peptone broth it appeared as a flocculent growth in which an abundant fine mycelium was present. Other workers also claim to have grown it; in 1926 Templeton reported that he had cultivated it on beerwort agar, and in 1929 Panja announced that he had succeeded in getting it to grow on scales as chalky points or pinkish bead-like masses in a medium consisting of equal parts of meat infusion in 15 per cent. glycerinated water and egg, tinged with gentian violet to inhibit the growth of staphylococci, and that in subculture he had been able to grow it on all laboratory media, but best on glucose agar.

Biochemical Reactions.—It ferments galactose with no gas formation, maltose with slight gas formation, and glucose with slight gas formation; it does not ferment saccharose, insulin, lactose, and mannite. Gelatin is not liquefied by it.

Cutaneous Lesions Caused by Pityrosporon.

(1) *The Scalp.*

On the scalp the pityrosporon produces the familiar condition variously known as dandruff, pityriasis capitis, or seborrhoeic dermatitis of the scalp. In its mildest form this affection occurs as delicate, pellucid, powdery scales, either present between the hairs or around them in the form of small collarettes, which are shed when the hair is brushed, and tend to fall down and collect on the coat collar. It begins as minute scaly patches, which extend and coalesce, and, as the affection is progressive, eventually cover the whole scalp.

In mild cases the inflammation of the scalp is so slight that no obvious signs of it can be detected, but in severe cases there is an inflammatory base, which extends beyond the scaly areas, and the scales themselves, instead of being fine and powdery, are coarse and greasy. In the affected parts the hair becomes lustreless and brittle, and tends to fall out, at first about the vertex and sides of the forehead, leaving bald areas, which gradually spread till only a fringe of hair is left at the sides of the head and the occiput, where it may persist long after the rest of the scalp has become bald.

In many of the cases the defluvium of the hair is associated with a greasy condition of the scalp due to an oily and waxy substance containing an excess of oleic acid or stearin, which oozes from the orifices of the follicles. The oiliness of the scalp may be aggravated by a hyperactivity of the sweat glands (hyperidrosis oleosa).

(2) *Glabrous Skin.*

The pityrosporon infection is liable to spread from the scalp on to the glabrous skin, and to be responsible for the different types of lesion which have been grouped together under the heading "seborrhoeic dermatitis." These consist of scaly papules, scaly patches on an inflamed basis, characteristic circinate or gyrate patches with a well-defined border of a brownish-yellow tinge and a smooth or slightly scaly surface, and eczematized patches situated chiefly in the flexures of the larger joints and in the intertriginous regions. These different types of lesion are due to individual peculiarities of the skin affected, differences in the situation of the lesion, and secondary changes from

rubbing, scratching, and the inoculation of septic organisms. From the scalp it spreads readily on to the forehead in pinkish scaly festoons (corona seborrhoeica), down behind the ears, and on to the nape of the neck. On the face it may occur as ill-defined, pinkish, scaly patches, or it may attack the eyebrows, margins of the eyelids, or moustache region, giving rise to chronically inflamed scaly patches. On the trunk it is frequently met with in the sternal and interscapular regions in the form of circinate or figured lesions, to which the appropriate name of pityriasis circinata has been applied, and which have for long been popularly known in this country as "flannel rash," since the wearing of flannel next the skin predisposes to the eruption, as it encourages the growth of the fungus by increasing perspiration and sebaceous flux, and by keeping the skin moist and clammy from its non-absorbent characteristics. It is also liable to affect the intertriginous regions—namely, the axillae, genito-crural fold, and interdigital spaces, and is not infrequent about the umbilicus, nipples, and scrotum, where it is liable to become cracked, moist, and eczematized.

Other types of lesions may be met with on the trunk, such as groups of small follicular papules with definite horny plugs or patches with a reddish border studded with minute vesicles. On the limbs it is generally most marked on the flexor aspects, especially the bend of the elbows and the popliteal spaces. On the scalp and trunk it is generally associated with itching, which is aggravated by heat, and which leads to scratching and eczematization, and in rare instances to exfoliative dermatitis.

Pathogenicity of Pityrosporon.

It is only recently that the pityrosporon has been established as the cause of seborrhoeic dermatitis. It occurs invariably in the different lesions of that disease, and is present in the scales of dandruff, in the scaly lesions about the trunk and intertriginous regions, in the circinate and gyrate lesions, and in the horny plugs in the follicular type of lesion, and is absent in other types of scaly dermatitis. Experimentally it has been proved to be pathogenic on the human skin and scalp, and to be non-pathogenic in the usual experimental animals, such as mice, rabbits, and guinea-pigs.

Though it had long been known that seborrhoeic dermatitis is auto-inoculable and capable of transmission from one person to another directly by contact, as in the case of a suckling infant infecting the breast of the mother, or indirectly by the medium of infected brushes, combs, caps, etc., and although it had been regarded as the cause of dandruff by Unna and others, it was only in 1928 that conclusive inoculation experiments proved its pathogenicity. These experiments were carried out by Dowling in the St. John's Hospital Laboratory, and are described in detail in a paper published by Dowling and myself in the *British Journal of Dermatology* (1928, xl, p. 139). The experiments were briefly as follows:

E. *Cxriment 1.*—A drop of suspension of the fungus in water among ected intradermally in patients with seborrhoeic dermatitis. regarded *ment 2.*—Organisms taken from cultures of pityrosporon dermatitis*lanted after light* scarification in patients with seborover the t*matitis and in controls on normal skin.*

alone in the scales, but generally in symbiosis with other organisms believed in the past to be pathogenic. These organisms are: (1) a slightly virulent staphylococcus known as the "grey coccus" of Sabouraud from the tint of its culture, or the "morococcus" of Unna from the arrangement of its cocci in mulberry-like clusters; (2) a small bacillus known as the micro-bacillus of Sabouraud or the acne bacillus of Unna which occurs in scales and scrapings from seborrhoeic dermatitis and in vast numbers in comedones.

The "grey coccus" is found chiefly in symbiosis with the pityrosporon in the more acute types of seborrhoeic dermatitis with greasy scales of both the scalp and glabrous skin, its precise relation to the lesions being undecided, but it seems most probable that it is of secondary importance and responsible for aggravating the lesions already produced by the pityrosporon by increasing the inflammatory disturbance. The micro-bacillus was believed at one time to be the cause of the comedo and also of seborrhoea, but is now almost universally regarded as non-pathogenic.

Another controversial factor in connexion with pityrosporon infections is the greasy condition of the skin due to excessive activity of the sebaceous glands, and to some extent of the sweat glands, known as seborrhoea. This is most marked where the glands are largest, as about the intertriginous regions, sides of the nose, auricles, etc. It was believed by certain writers to be a pathological condition, and it has even been suggested that it is of microbic origin; Sabouraud, for example, attributing it to the micro-bacillus. Its importance lies in that it renders the skin a favourable soil for the growth not only of the pityrosporon but of staphylococci, such as the grey coccus, the excessive growth of which may be largely responsible for transforming rather insignificant scaly lesions into acute inflamed itchy patches covered with greasy scales.

The microbic theory of the origin of seborrhoea, however, is no longer tenable, and it is now believed to be essentially a physiological process which becomes active in most individuals about puberty in association with the appearance of hair in certain regions of the body, and may persist through early adult life, but which may be met with also as a hereditary peculiarity running in families, an idiosyncrasy, or an acquired condition the result of a dyscrasia due to some endocrinal derangement, or of a faulty dietary with an excessive fatty or carbohydrate intake.

The exact mechanism by which the falling of the hair takes place in seborrhoeic dermatitis of the scalp is uncertain. It has been attributed on the one hand to the direct action of the pityrosporon, and on the other hand to the underlying seborrhoea. A third suggestion is that it is due to an interference with the balance which normally exists in the pilo-sebaceous follicle between the hair and the sebaceous gland, and that when the gland becomes hyperactive and hypertrophic the hair itself undergoes a compensatory atrophy.

BLASTOMYCES.

Another pathogenic yeast-like fungus is the blastomyces, so named by Gilchrist in 1894, a fungus of which we have had comparatively little experience in this country. The cases of infection by it have nearly all been in America, and only a few have so far been reported here, though in all probability others have occurred which have escaped recognition.

This fungus is nearly related to the pityrosporon, and is one of the pathogenic cryptococci. It is readily found in the crusts and sero-purulent discharge from the lesions caused by it and in small abscesses in the tissues.

It occurs as round or oval bodies, arranged singly, in pairs, or in small groups, 5μ to 10μ or larger in diameter, with a single or double wall and a fine granular protoplasm.

In culture it shows a rudimentary mycelium with short pod-like segments containing spores. It reproduces itself either by budding from spores or by lateral and terminal conidia or short hyphae, but never by the formation of asci. It grows on ordinary media; on glycerin agar it appears in about seven days as greyish-white colonies, and on blood agar at 37° C. it has been grown in three days as small cream-coloured colonies. It neither liquefies gelatin nor ferments sugar. It is pathogenic in man, and in mice, rats, guinea-pigs, sheep, etc. When introduced intraperitoneally in experimental animals it gives rise to a systemic infection with the formation of abdominal nodules and frequent involvement of the testicles.

Lesions in the Skin Produced by the Blastomyces.

The lesions in the skin caused by the blastomyces, constitute what is generally known as blastomycetic dermatitis. They begin as groups of small, reddish-brown nodules, which increase and coalesce to form irregular patches, which may be dry and hard or moist and soft, and are separated by fissures from which oozes a sero-purulent or sanguineous discharge, which wells out when the patches are squeezed. The borders of the patches are well defined and abrupt, and usually slope gradually down to the healthy skin. The lesions so closely resemble the verrucose type of tuberculosis cutis that they are usually mistaken in the first instance for it, and the diagnosis is only established by the discovery of the fungus.

The patches are usually multiple, are spread by autoinoculation, and are most commonly situated on the face, hands, back, and legs. Histologically they are verrucose granulomata with minute abscesses in the epidermis and corium, where the fungus can usually be detected. The infection, as a rule, remains local without glandular involvement, but in rare instances it has been known to become generalized and to invade the internal organs, with the production of multiple abscesses.

Under suitable treatment with potassium iodide retrogressive changes may take place, with the formation of red, shiny, smooth cicatrices, which may completely or partially replace the whole lesion.

COCCIDIOIDES.

The "*Coccidioides immitis*" of Rixford and Gilchrist is the last of the yeast-like fungi to which I wish to refer.

It is a more highly developed fungus than the blastomyces, belongs to the family of the Endomycetaceae, and forms a connecting link between monilias and true yeasts. It occurs in the tissues as variously sized, rounded bodies, much larger than blastomyces, of 10*u* to 30*u* or larger in diameter, some of which contain spores. It grows slowly on dextrose peptone agar in the form of a milky white culture, which subsequently becomes cream-coloured. It reproduces itself by endosporulation in the tissues, the spores being small and capable of dissemination through the blood stream and lymphatics, and in culture it shows mycelial threads, which may be branched or straight, and asci.

The fungus is found in the discharge from cutaneous lesions, in the pus from abscesses, and where the infection has become generalized in the sputum, blood, urine, and faeces. In the tissues it may be found in small abscesses or in the midst of the granulomatous infiltration, either free or in giant cells of the Langhans type, in the form of round or oval bodies, sometimes containing a large number of spores. The fungus does not ferment sugars. It is pathogenic in man, and in the lower animals, such as mice, rabbits, and guinea-pigs.

Unlike the blastomyces it usually gives rise to a general infection which only occasionally originates in the skin, and most frequently takes place through the lungs and affects the skin secondarily. Cases of the infection have been described in the past under various headings, such as saccharomycosis, coccidioidal granuloma, and dermatitis coccidioides, and have occurred chiefly in California, where as many as 160 have been reported. Its most marked feature is the presence of multiple abscesses situated in the skin and internal organs.

In the skin it appears as crops of small nodules, pustules, or occasionally verrucose papules about the size of a pea, which become red, enlarge, soften, and break down, forming ulcers with an unhealthy granulated floor, from which oozes a purulent discharge which dries up to form crusts.

The internal abscesses are present chiefly in the lungs, liver, kidney, and spleen, but may be met with also in the muscles and may cause necrotic changes in the bones. The presence of abscesses in the lungs may give rise to symptoms suggesting tuberculosis, and in the kidneys and intestine to albuminuria and diarrhoea, and the neighbouring lymphatic glands are invariably enlarged. As a result of septic absorption an irregular temperature and malaise occur, and death usually supervenes from pyaemia.

CONCLUSION.

These four yeast-like fungi which we have had under review must be regarded simply as types, for just as there are variants of the ringworm fungus, so there are variants of the monilia, blastomyces, and pityrosporon, but the variations which occur are so apt to be inconstant that their precise classification in the present state of our knowledge is almost an impossibility.

SOME OBSERVATIONS ON THE MENTAL DEVELOPMENT OF FEEBLE-MINDED CHILDREN.

BY

R. G. GORDON, M.D., D.Sc., F.R.C.P.ED.,

AND

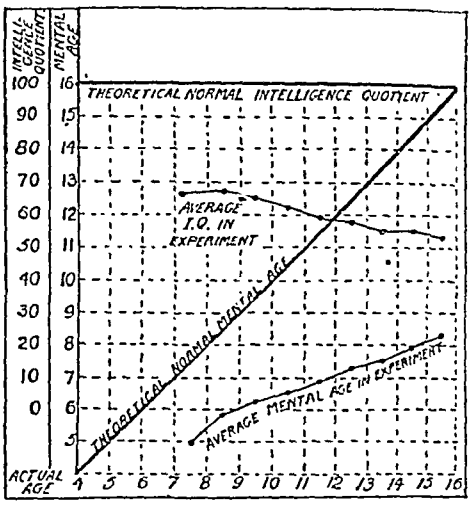
R. S. THOMAS, M.D., D.P.H.

DURING the last nine years periodic examinations have been carried out to discover what educational progress, if any, is made by children who have attended the special school for defectives in Bath. Under the Education Acts, it is incumbent on local authorities to provide a special school for those children who, in the opinion of the school medical officer, are incapable of benefiting by education in the ordinary elementary school, but are not so deficient in intelligence or adaptability as to be totally unable to fend for themselves. In other words, the school provides for those children who legally come under the category of feeble-minded. In practice the child is referred from the ordinary school as being probably unable to benefit by instruction at that school, and must have reached the age of 7 before he is allowed to be dealt with by certification. He is examined by a school medical officer, using the Terman scale as the criterion, and if in his opinion he can be classified as feeble-minded, he is certified as such, and sent to the special school. In the course of the present investigation it has been found that quite a large number of children admitted to the special school have proved to be imbeciles—that is to say, they are not able to fend for themselves in life, and therefore must be cared for in some way or other, either by being sent to special residential institutions, or by being placed under the protection of some specified guardian, who may be the parent. This guardian is responsible for the protection of the imbecile against himself and society, and of society against the imbecile. At the age of 7 children may appear likely to turn out to be imbeciles, but where there is a doubt on the subject the child is naturally given the benefit of that doubt, both on humanitarian and economic grounds, and afforded a chance of improvement at the special school. If, as often happens, such children do not improve, it becomes necessary to hand them over to the care of the statutory mental deficiency committee, which is responsible for dealing with imbeciles by sending them to institutions, or putting them under special guardianship, or by supervising them in their own homes.

The special school under discussion contains on an average 45 children—25 boys and 20 girls. They are taught very slowly along ordinary lines up to the level of Standard II or a poor Standard III of the elementary school, and at the same time practical manual work is encouraged. The staff of the school consists of two specially experienced teachers of ordinary school subjects, and of instructors in bootmaking, carpentry, and domestic subjects respectively. The size of the individual classes varies with the number of children being taught in the special departments at any given time. The education authority has power to retain children in a special school until the age of 16.

During the period under review 66 children passed through the school and were discharged as follows: 27 per cent. were passed to the statutory mental deficiency committee as imbeciles—that is to say, they proved unable to fend for themselves in life; 36 per cent. were classified as low grade feeble-minded, probably unable to fend for themselves; and 37 per cent. were considered able to fend for

themselves and not notified to the statutory committee. The actual results up to the end of 1925 are known as regards 52 children, of whom 42 per cent. are at work fending for themselves, 10 per cent. are out of work, apparently failing to fend for themselves, 25 per cent. are at home incapable of work, and 23 per cent. are in institutions. It may be noted that the prognosis of the school medical officer in consultation with the head teacher underestimated the number able to find a position in the labour market.



So far as the present inquiry is concerned 82 children were examined by the Terman method, which aims at discovering not only their intellectual capacity, which is a measure of their power of receptive activity, but also their manual dexterity or power of effective activity, and their general capacity for adaptation to life. Long experience and elaborate statistics show that on the whole this test, if it is carried out by an experienced observer who is prepared to use his judgement in the interpretation of results, does afford a very fair indication of the child's general capacity. The scoring of the test establishes the child's mental age (M.A.), by which is meant the age of the average normal child who might be expected to have the same general capacity as the child under observation is proved to possess, and the intelligence quotient (I.Q.), by which is meant the relationship between the actual age and the mental age of the subject under examination. On this reckoning the normal child will have an I.Q. of 100, the precocious child an I.Q. of 100 upwards, and the backward child an I.Q. of less than 100. Of these 82 children, 78 (32 girls and 46 boys) were cases of primary amentia—that is, they had a developmental defect not due to intercurrent disease or injury—while 4 were presumably cases of secondary amentia, 1 (a boy) having a history of birth injury, and 3 (2 girls and 1 boy) of congenital syphilis. Of the 78 cases of primary amentia, 61 were not complicated by other defects. Of these, 31 boys were feeble-minded and 5 were imbeciles, while 20 girls were feeble-minded and 5 were imbeciles. Of the cases complicated by other defects, 2 might possibly be taken out of the category of amentia altogether. Of these, one was a boy with word blindness and idioglossia—that is, word deafness—and the other a boy with severe cerebellar ataxy.

Definite conduct disorder was noted in 7 cases (4 boys and 3 girls), one of the boys being also a haemophilic. This almost exactly tallies with Cyril Burt's estimate of an 8 per cent. correlation between delinquents and certifiable defectives. One girl had severe heart disease, one girl had severe defective vision, and one girl was a cripple. One boy had a severe stammer, one boy was epileptic, and one boy had a cleft palate. It would appear, therefore, that the correlation of gross physical defect with mental defect is not high, though the incidence of minor ill health among mentally deficient children is high. In children with primary amentia this is usually found to be the case. Two children in this group (one boy and one girl) were of the mongol type of mental defect.

In the investigation Terman tests were performed at more or less regular intervals of twelve months on each child, and naturally the M.A. of these children was considerably below their actual age on the first examination. The I.Q.'s on admission to the school were as follows:

I.Q.	Individuals.
80	... 2
75+	... 4
70+	... 13
65+	... 16
60+	... 23
55+	... 7
50+	... 11
45+	... 5
45-	... 1

In the series, therefore, 69.7 per cent. ranged from an I.Q. of 60 to 75 on admission, so that on the average the children had rather less than three-quarters of the capacity which they ought to have had for their age. On subsequent examinations the progress was neither uniform nor consistent with their age development. If reference is made to the accompanying graph, which does not include the imbecile children, it will be seen that the theoretical average advances in mental age one year for every year advanced in actual age, although in practice the advent of puberty and other causes are apt to disturb this completely symmetrical progress. The defectives do not gain a year in mental age with a gain of a year in actual age, and consequently their I.Q. always tends to drop, although in one-third of the children the I.Q. actually shows a rise after their admission to the special school, probably because they are taken away from an atmosphere of unfair competition with other children who they cannot but feel are superior

to themselves. Sometimes it was found that there was no progress whatever from one year to another, but this check was only temporary, and on the whole they definitely, though slowly, advance in mental age right on to 15 years and over, thus showing progress for fully as long a period as the normal. It is interesting to note that in only five cases was there ever an actual drop in the M.A. from one year to another. One girl lost two months between 10 and 11—her present age. One girl showed a drop of two months from 11 to 12, regained the loss between 12 and 13, and then gained six months from 12 to 14. One girl lost two months between 14½ and 15½, but at this age tests are perhaps less reliable. One boy similarly lost two months between 15 and 16. One mongol boy lost a year between 13 and 14, but mongols cannot be considered quite in the same category as ordinary defectives, as the causal factor in the genesis of this very specialized type is not known. If, as is sometimes supposed, congenital syphilis is responsible for the mongol, deterioration at about puberty may be expected, for it is by no means uncommon in other varieties of congenital syphilitic lesions.

The exceptions are so slight that they may be neglected in a generalization that these defectives do progress in a slow but definite manner in the acquisition of general capacity with advancing age right on to 16 years of age. As Sherrington has shown, a child is born with his complete complement of neuroblasts. These neuroblasts are potential neurones or nerve cells, which can only function when they acquire their medullary sheaths. The formation of the functioning neurone appears to be the direct result of interest associated with stimuli derived from the body itself, or from the environment through the organs of common sensation, and more particularly through the distance receptors—sight, hearing, and to a less extent smell. The mentally deficient are no exception to this rule, for they also require to have their neuroblasts converted into functioning neurones, and it is only when the requisite stimuli can be provided and the necessary interest aroused that this can occur. It is reasonable to suppose that such stimuli can be supplied and interest aroused to better advantage when the children are put to tasks within their capacity than when they are subjected to the unfair competition of the ordinary school.

The accompanying graph shows the composite results of the inquiry. In this boys and girls are taken together, and they show a flattening of the curve of progress about the years 11½ to 13½, with a continuation of a rising curve from

15 to 16. In boys the flattening starts at 10½ and continues to about 13½, but the rise to 15 to 16 is quite striking. In girls there is a flattening from 9½ to 10½, and again at 12½, but the late rise is not so marked, though sufficiently obvious. The influence of puberty on the slowing-down periods is, of course, purely inferential, but it is at least suggestive; while the continued rise—which appears to go on after the child leaves the school, since the number of successes exceeded expectation—may be due to a variety of causes. It may be that in the later years of training more attention is paid to manipulative work, and that this develops an inherent power for such performances, which has not previously been given a chance, and so gives more opportunity for the reception of stimuli and arousing of interest necessary to convert neuroblasts to neurones. It must be remembered, however, that the Terman tests are by no means purely intellectual in their scope, and should record capacity for manipulative and intellectual advance apart from achievement, though unless neuroblasts have been converted capacity will remain undiscoverable. On the other hand, the continuance of progress is in accordance with the finding of a previous investigation we made into children of slight degrees of backwardness. This showed that while many of these children failed to adjust to the requirements of life during the school period, they made remarkably good adjustments later on in late adolescence and early adult life. The 15 and 16 year olds may be approaching this period of more successful adjustment, and therefore make a better showing in their tests than might have been expected from the common supposition that mental defectives stop short in their development. The following tables show the findings at the various ages exclusive of the imbeciles.

TABLE I.—*Boys and Girls together (82 Children).*

Certain points in addition to the continuance of progress stand out in relation to these tests. The early improvement in capacity after admission to the special school illustrates the necessity of removing backward children from competition with normal children of their age, since this always causes them to be discouraged and renders them sullen or mischievous. The low correlation with gross physical defect and conduct disorder is of interest in so far as it fits in with proved statistical records, which are, however, often looked on askance by the medical and lay public because they do not conform with certain preconceived ideas. The whole nature and development of mental defectives is interesting in relation to certain physiological experiments on rats. Mental defect is held to be due to a relative absence of the higher level cortical cells—an amentia. The failure is proved on post-mortem examination to be fairly general in distribution throughout the cortex, and is not localized in any one area. Although these cells are not there to develop, and no new cortical neuroblasts are ever laid down after the period of infancy, the capacity of the child does improve, though slowly, provided he rises to a level above the imbecile. The cells that are present must therefore to some extent assume the functions of those which are missing, for even the conversion of all the neuroblasts present is probably not enough. Professor Lashley and his colleagues have shown that it is comparatively easy to teach rats to find their way through a maze; that when various parts of the cortex are destroyed the rats can still be taught to run the maze, but with greater difficulty. They have, moreover, shown that the difficulty depends not on the localization, but on the extent of the injury, and that, so far as the function of maze learning is concerned, it is a property of the cortex as a whole rather than of any particular part, and that the remaining cells are capable of undertaking, at any rate to some extent, the functions of those which have been destroyed. The analogy between the history of mental defectives and the rats of Lashley's experiments is very striking.

The extent to which it is worth while expending money on the teaching and training of mental defectives is a question which is likely to give rise to a considerable amount of controversy, but the fact that 42 per cent. of the children trained in this particular special school were able to find work, and that only 23 per cent. had to be placed in institutions, is at least encouraging; but even so, there can be little doubt that the colony system on a large scale is the optimum method of dealing with certifiable mental defect in the bulk.

SEPTICAEMIA AND ENCEPHALITIS IN RELATION TO VACCINATION.

BY

F. TEMPLE GREY, M.B., CH.M., PATHOLOGIST, AND W. M. WHITTAKER, M.D., HOUSE-PHYSICIAN,*

EAST LONDON HOSPITAL FOR CHILDREN.

ANYONE who has followed at all closely the history of post-vaccinal fatalities must have been struck by the fact that, until recently, these patients, as a general rule, died from septicaemia, whereas now they die from encephalitis. Much more research than that which has been published is required to determine whether any causal relation exists between vaccination and the encephalitis reported as occurring in such cases, and, if so, what is the nature of such relation.

Of the sixty-two post-vaccinal cases of acute nervous diseases considered by the Ministry of Health Committee in 1925, only six were submitted to post-mortem examination and studied histologically. Meagre details were forthcoming in the majority of cases, and in no case was a blood culture performed either before or after death. It is not surprising, therefore, that the majority of the committee referred to hesitated to find proof of any direct causal relationship between vaccination and the deaths following shortly thereafter. In a minority report, however, the opinion was expressed that there was such a relationship. The medical profession would appear to have ignored the majority report and to have accepted the minority report, for this is the only explanation we can

* Reciprocity with Barnes Hospital, St. Louis, Missouri, U.S.A.

find of the curious fact that all such deaths are now reported as "post-vaccinal encephalitis."

Such a case came before us recently when one of us (T. G.) was asked by the coroner for East London (Dr. Guthrie) to make a post-mortem examination on a patient dying in the East London Hospital for Children after vaccination and reported to the medical officer of health as a case of "post-vaccinal encephalitis." The patient was under the immediate charge of the other of us (W. W.), and, in accordance with the usual clinical routine in any case presenting obscure generalized symptoms, a blood culture was made in two broth tubes and on an agar plate, *Staphylococcus aureus* being found in all media. The details are as follows.

A girl, aged 10, was admitted on July 27th, 1929, under Dr. Geoffrey Bourne with a temperature of 103°; she had been vaccinated on July 23rd by the public vaccinator, who used Government lymph, two insertions being made in the left deltoid region. Another child in the family was vaccinated at the same time. The girl seemed to be fit till the evening of July 26th, when she complained of pains in her head and abdomen, followed by two or three attacks of vomiting. She was feverish, but rested well at night. On the morning of July 27th she had a chill and was feverish; she became delirious and very drowsy. The drowsiness persisted all day, and she vomited again. There had been no fits or convulsions, nor any history of recent infectious diseases. She had had measles when 2 years old, and chorea at 5, but she was apparently in good health when vaccinated, and was well nourished.

On examination she was found to be prostrated and semi-conscious, being aroused with difficulty; there was no rash or eruption, except a small, reddened, indurated area over the right tibia. Her colour was good; the respiratory rate was somewhat increased, but there were no rhonchi. The breath was foul, with no odour of acetone; there was marked trismus, and the pharynx was seen with difficulty. The air entry was slightly lessened over the right side of the chest; the percussion note was somewhat flattened, but there were no added sounds. On percussion the cardiac area was found to be normal, and the pulse was thready, 150 to the minute; there was no murmur and no friction rub. The abdomen was soft, and the spleen and liver were not felt. There was no oedema of the extremities, or evidence of paralyses or spasticity. The ear drums were normal, but the pupils were widely dilated, the right reacting to light and accommodation, while the left was fixed; no ptosis was noted, and no facial paralysis, but there was intense papilloedema of the fundi, the disc outlines being very blurred and the vessels greatly engorged. The corneal reflex was intact on both sides. The arm reflexes were normal, but the abdominal reflexes were absent; the knee-jerks were sluggish, there was no ankle clonus, the plantar reflexes were flexor, and the Brudzinski sign was present.

The laboratory findings were as follows:

Blood count: Leucocytes 33,400 per c.mm.; polymorphs 90 per cent.; lymphocytes 9 per cent.; and myelocytes 1 per cent. There were many young polymorphs of the single-lobed variety, with a definite shift to the left in the Arneth count.

Catheterized urine: Acid reaction; protein 0.5 per cent.; no glucose; trace of ketones; no blood; no deposit.

Lumbar puncture: 10 c.cm. of slightly hazy fluid was withdrawn, and no coagulum formed in incubating; the count was 75 cells per c.mm., 90 per cent. of which were lymphocytes; smears showed no tubercle bacilli or other organisms; there was no growth on culture; the protein content was 0.06 per cent., and the chloride content estimated as sodium chloride was 0.64 per cent.

Blood culture: Staphylococcus aureus was recovered. The blood urea figure was 80 mg. per 100 c.cm.

The child remained comatose, but the temperature rose to 104–105° F.; the pulse was hardly perceptible, and the reflexes remained unaltered. Milk and sugar solutions given by the nasal tube were all vomited. Clonic convulsions of the arms and legs developed, with considerable opisthotonos and cyanosis, and the child died on July 28th.

At the post-mortem examination the signs of recent vaccination were apparent as two raised papules over the left deltoid; the lesions were clean. The face and neck were flushed, the tongue was furred, and there was early green discoloration of the abdomen. The middle and lowest lobes of the right lung were adherent posteriorly and to the diaphragm; all lobes were congested except the upper left one. The heart muscle, liver, and kidneys showed cloudy swelling; and there were numerous vegetations of the mitral valve. A Giemsa-stained film of the heart blood revealed numerous staphylococci. The spleen, which was large and firm, contained several infarcts, and the pancreas was injected. The appendix was bound down behind the caecum, and kinked. The stomach contained a small amount of material indistinguishable from intestinal contents; there had been some retroperistalsis, and a small amount of this material was present in the oesophagus and right bronchus.

The brain surface, which was much engorged, was dotted with multiple pyaemic abscesses from which staphylococci were isolated. The meninges of the brain and cord were injected, and the cord was somewhat soft. No macroscopic lesions of the brain or cord substance were detected, and there was no disease of the middle or inner ear.

Death in this case was due, then, to septicaemia and pyaemia. It will be seen that the scepticism with which the fashionable diagnosis of "post-vaccinal encephalitis" was approached was amply justified, and but for the inquiry this case would have found its way into the statistics as one of "post-vaccinal encephalitis."

Another case, attributed by the friends and neighbours (but not by any medical practitioner) to vaccination eighty-six days before death, was investigated by one of us (T. G.) for the North-Eastern district coroner (Dr. Edwin Smith). The details are as follows:

A man, aged 20, was vaccinated on May 18th, 1929. He was treated in May and June for a febrile condition beginning two days after vaccination. He was examined by another doctor on July 16th, two teeth having been extracted the previous day; he was diagnosed as having influenza, and was seen frequently till July 30th, when he was admitted to a municipal hospital with a temperature of 101.4°. Swelling and ulceration of the gums was then present, with suppuration round all the teeth; there were enlarged tender glands on both sides of the neck and in both groins. The spleen was large and tender. The temperature fluctuated between 102° and 104°, and no improvement in the mouth condition resulted from conservative treatment. Complete dental extraction was performed under general anaesthesia on August 1st, but no improvement followed, and the patient died on August 12th.

At the post-mortem examination four recent scars were observable in the left deltoid region, presumably due to vaccination. The inguinal glands were enlarged. The mouth was in a septic condition, and the tongue was covered with sordes; the jaws were edentulous (recent extractions); and osteomyelitis was present. Bacteriological examination revealed large numbers of staphylococci and streptococci, besides a few saprophytes. There was an enlarged gland in the right anterior triangle of the neck. Four ounces of blood-stained fluid was found in the peritoneal cavity. The spleen was much enlarged (24 oz.), as were the mediastinal glands; 8 oz. of blood-stained fluid occupied the left pleural sac, and there was 10 oz. in the right, but no pleurisy or chronic pathological process (macroscopic) was detected in the lungs. Some broncho-pneumonia was present, but no oedema of the glottis.

The kidneys showed macroscopic changes suggestive of leukaemia; sections revealed lymphatic leukaemia, as did sections of the spleen, liver, and brain. There was 4 oz. of blood-stained fluid in the pericardial sac; the heart was flabby, and some myocarditis was present; the vessels were healthy except for scattered atheromatous patches about the aortic valves. Microscopic examination of the blood films showed a lymphatic leukaemia and the presence of staphylococci.

Death was apparently due to septicaemia and osteomyelitis in a case of lymphatic leukaemia.

Since by hypothesis septicaemia and pyaemia can hardly be without effect on any and every tissue of the body, it is an extraordinary thing that the histologist has, with rare exceptions, so little to tell us about the state of the brain and spinal cord in these conditions. Diamond[1] stressed the point that in septicaemia one finds no organism in the brain, although histological examination reveals multiple areas of softening due to a toxin reaction, and not to any definite infiltration of the brain by organisms. These changes he likened to those of disseminated sclerosis. But the changes in post-vaccinal encephalitis have been compared with those in disseminated sclerosis (Turnbull and McIntosh[2]).

On the other hand, although the histology of encephalomyelitis, with its characteristic areas of demyelination, is now on a satisfactory basis, it must constantly be borne in mind that these changes can occur apart altogether from vaccination.[3]

Conclusions.

1. No condition can be fairly described as encephalitis pure and simple unless septicaemia has been excluded as a possible cause by appropriate bacteriological examinations.

2. All cases of severe illness within three weeks after vaccination should be under hospital treatment, in order that the necessary special examinations may be performed; should death occur, the necropsy should include bacteriological and histological investigation of the other tissues as well as those of the central nervous system.

3. Only when a larger number of cases have been examined in a uniform and careful manner can any conclusions be

safely adopted. Meanwhile, it may be fair to suppose that vaccination can light up a dormant infection such as low grade septicæmia.

4. The comparative immunity of infants to complications after vaccination would appear to be due to the fact that they are hardly likely to be harbouring such an infection. As for the still not uncommon gross infection of the vaccination site, young infants are obviously unable to set up such a condition, since they cannot scratch their own arms.

PRIMARY CARCINOMA OF THE APPENDIX.

BY

E. W. M. H. PHILLIPS, D.M., M.Ch.Oxon, F.R.C.S.Ed.,
HONORARY SURGEON, PORT TALBOT HOSPITAL;
AND
DONALD H. ISAAC, M.R.C.S., L.R.C.P.

MALIGNANT disease of the appendix is of some special interest, not only by reason of the popular idea as to its rarity, but also because of the histological and other problems which are concerned. It may therefore be worth while recording a case which illustrates some points of importance in these respects.

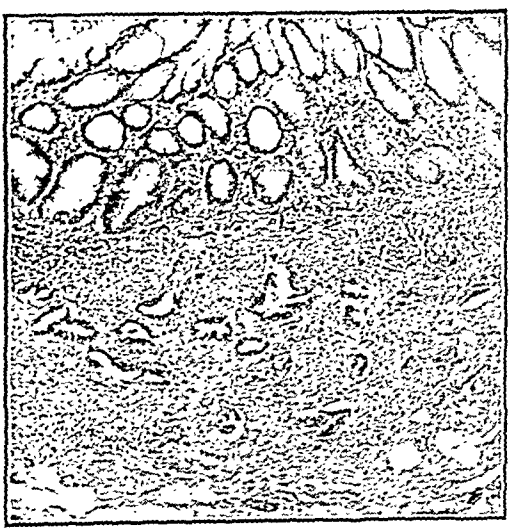

FIG. 1.—Growth in the appendix.

A multipara, aged 56, who had lost one sister from carcinoma of the cervix, but whose personal and family history was devoid of tubercle, sought belated advice for colicky pains and distension, variable in relation to meals; the condition was becoming more constant, and never exhibited periodicity. She gave a history of previous indigestion over a period of some years, sometimes interspersed with fairly severe and prolonged colic. Medical advice she eschewed on the representations of officious friends, who feared for her the "way of the knife." Her symptoms gradually became more severe, and the supervention of some wasting and occasional bouts of vomiting made a consultation imperative. She was constipated; she never at any time suffered from alternating diarrhœa, nor was there ever any declared blood in her stools.

Physical Examination.—The woman was pale and cachectic, and there was loss of dermal elasticity. Her regular pulse of 90 was of a suitset softness in quality. No chest lesion was detectable. The upper abdomen showed a little fullness, and peristalsis could just faintly be discerned. Liver dullness was normal, and no splenic enlargement could be made out. It was observed that while no caput medusæ was in evidence, the protruding umbilicus, quite small, had a nodular cartilaginous feel. In the right iliac fossa there was an indefinite hard mass, freely movable through a small arc of a circle centred at the umbilicus, though not along its radius. The swelling, about the size of an orange, presented no graded upward margin, as in ileo-cæcal tuberculosis, and it appeared to be of uniform consistency. Pelvic examination shed no further light, nor was there any enlargement of the ovaries. Owing to temporary disorganization of plant, and the comparative urgency of the case, radiography was dispensed with. The diagnosis, indeed, seemed clearly to be adeno-carcinoma of the cæcum, or possibly the formative type of ileo-cæcal tuberculosis, either alternative offering a reasonable hope from surgical intervention.

Operation.—A low paramedian coeliotomy was performed, and a little free fluid escaped. The most striking feature was a hardened nodular cake-like mass, consisting of omentum, obviously infiltrated with growth, and receiving at the umbilicus a small but firm attachment to the anterior abdominal wall. From this region it was carried downwards to adhere to, to cross superficially, and to kink, almost to the occlusion of its lumen, the lower four inches of the ileum. From here it proceeded to the appendix, which in part it clothed, and to which it firmly, but sparingly adhered. The appendix, twisted upon itself, presented three ovoid swellings, cartilaginous to the feel, measuring 1 by 1.5 cm., serially arranged in apposition like a string of beads. The mesentery of the appendix was short, thick, and infiltrated with excess of fat. The appendicular lymph nodes were not enlarged, nor indeed was there any evidence anywhere in the abdomen of glandular involvement, save in the portal fissure, and here it formed a noteworthy feature. The serous coat of the appendix was much thickened, but retained its sheen, and was typically pearly. Macroscopically there was no involvement of the cæcum, which was connected to the oval masses by a short length of apparently normal appendix. Systematic and meticulous scrutiny excluded all other of the abdominal contents than the appendix as the *fons et origo* of the primary neoplasm. The precarious state of the patient, no less than the infiltration of the whole of the great omentum and the involvement of the lymph nodes in the portal fissure (a seeming anomaly), precluded further surgical procedure than the removal, *secundum artem*, of the appendix and the freeing from its omental embarrassment of the involved segment of the ileum.

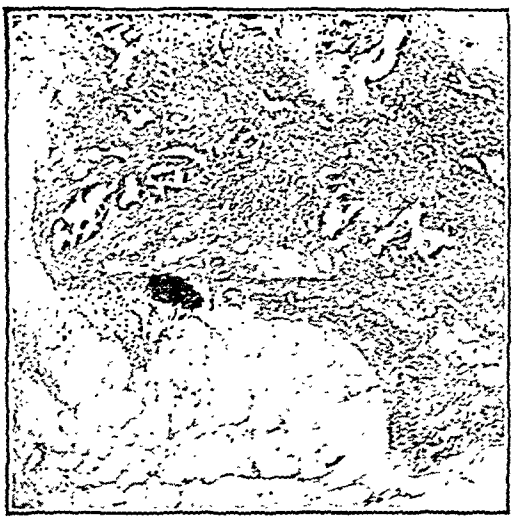

FIG. 2.—Growth in the great omentum.

Morbid Histology.—For the following pathological report on the condition of the appendix and the omentum we are indebted to Dr. Arthur Sladden, director of pathology at Swansea Hospital: "Sections of the appendix show the presence of a growth of the adeno-carcinomatous type infiltrating the whole of the submucous coat. The cells are regular, uniform, and cubical. The portion of omentum submitted for examination exhibits diffuse infiltration with a neoplasm whose cells are of the same general type."

The appendicular neoplasm is generally looked upon as a rare condition. The Mayo Clinic papers, however, place its incidence at 1 in 225 of all cases of appendicitis necessitating operation. Although this figure would seem a little pessimistic, and perhaps not quite in accord with common experience, the growth cannot be so uncommon as one might suppose. Many more examples would undoubtedly be revealed if all appendices removed were submitted to histological investigation.

Much controversy has centred in the phylogeny of the yellow tumour of the appendix, with its characteristic ring

of infiltration of the submucosa. Some, notably Aschoff, relegate it to the angioblastomas. Its cells are so ordered, flattened, and clear that this conclusion is tempting. Other histologists, interpreting these cell appearances as results of low grade anaplasia and tissue pressure, regard the growth as carcinomatous, but of such low malignancy as never to occasion metastases, nor, in the words of Boyd, "to cause the death of a patient."

This case shows that under unfavourable conditions, of which the time factor is one, an appendicular neoplasm can at least infiltrate, and has encompassed the death of a patient. It is evident that this growth, or its probable predecessor, chronic appendicitis, had been troubling our patient for years, and, unfortunately for her, not very severely. Indeed, but for the fortuitous offices of her over-zealous "policeman of the abdomen," the great omentum, she might yet be harbouring a neoplasm of the appendix, still "benign," with little to show for it beyond dyspepsia.

In 90 per cent. of all cases the incidence of the morbid process is at the tip of the appendix. More fortunate, however, is the lot of the 10 per cent. in whom it is found (incidentally and accidentally) in the proximal part, for in this region the early narrowing of the lumen leads to appendicitis of the obstructive type, calling for immediate intervention and its removal out of harm's way, as in the series of cases recorded by Wilkie.

It may be argued that our case is in no way comparable with the typical appendicular neoplasm; that, indeed, it bears the stamp of an evident adeno-carcinoma such as may be found anywhere in the alimentary tract. If that is so, it must be unique and all the more interesting. It must be admitted that macroscopically it is only by straining the imagination that we could describe its colour as yellow. From its histological appearances we should prefer to suggest that it is transitional between the hitherto described "benign carcinoma" of the appendix and the frankly malignant group of alimentary adeno-carcinomas in general. Microscopically, it bears an undoubted resemblance genetically to the so-called "benign carcinoma"; but it has infiltrated, and it certainly exhibits rather more anaplasia in the omentum, where tissue pressure relaxes, and the cell, ever impatient of restraint, automatically becomes more wayward.

ETHER CONVULSIONS.

BY

W. STANLEY SYKES, M.A., M.B., B.Ch., D.P.H.,

ANAESTHETIST TO THE LEEDS GENERAL INFIRMARY.

CONVULSIONS during anaesthesia are rare, but when they occur they are both dramatic and dangerous. The tragically sudden death of one of my own patients aroused in me a desire to know more about this subject, and led me to make the following collection of existing theories. My own case corresponds very closely indeed with those described by Wilson[1], and may be taken as typical.

The patient was a young adult, aged 28, with a septic lesion (pyosalpinx). The induction was uneventful, and the anaesthesia proceeded without incident for thirty to forty minutes. Suddenly, without previous cyanosis or warning of any kind, twitchings of the face appeared, which spread to the arms and legs until the whole body was in clonic convulsions and the patient had to be held on the table. There was no primary failure of the heart or respiration. Cyanosis did not occur until convulsions had been in progress some time, and was only slight. Death took place before it was well marked. (The death rate is nearly 25 per cent. in the recorded cases. It must be clearly understood that the convulsions come on when the patient is properly under.

Most of the published accounts regard the convulsions as an entirely new phenomenon, the first crop of cases occurring in 1925-26. One observer,[2] however, saw five cases between 1913 and 1925, so that this is not strictly true. Another case is on record dating from 1922. It is certain, however, that they are much more common now than formerly. It may be argued that they occurred before, but passed unnoticed because of their rarity, and it is true that even now they are very rare. McCardie[3] in thirty-two years' anaesthetic practice never saw a case at all, and many other anaesthetists of vast experience are in a similar position. I have seen one case in nearly 5,000 administrations. On the other hand, it is the rarities which get described in the journals, and ether convulsions are so *unprecedented and so fatal that it is justifiable* to assume their incidence before 1925 to be infinitesimal, or some of them would surely have been reported. Delayed chloroform poisoning is also extremely rare, and not nearly so evidently connected with anaesthesia as these convulsions are, but in spite of this it has been known to the textbooks for decades.

Theories of Causation.

The obscurity of the subject is well illustrated by the number of theories purporting to explain it.

Muskens[4] states: "In my book *Epilepsy* I have been able to assemble evidence . . . to prove that the period of transition from unconsciousness to consciousness, as in waking from sleep, is the period *par excellence* for the occurrence of epileptic phenomena. Further, a latent tendency to epileptic manifestations is frequently betrayed for the first time at this period. . . . The period of transition from unconsciousness induced by a narcotic . . . is associated with the same tendency. . . . The evidence afforded seems to me to suggest the question: Why are epileptic manifestations so comparatively rarely seen in persons emerging from narcosis?"

This hypothesis alters the facts to fit the theory. Ether convulsions begin *during the surgical stage of anaesthesia*, and not during the emergence from narcosis. Their most startling and characteristic feature is the sudden occurrence of movements in a person who ought, by all previous experience, to be absolutely immobile. In every recorded case the convulsions began when the patient was either stated or implied to be under. My own case was sufficiently under for the surgeon to sew up the peritoneum without comment. Muskens is either confusing the condition with true epilepsy (during induction or recovery) or with the harmless ether tremor of light anaesthesia. It bears no resemblance whatever to this or to the jactitations of gas administration. Incidentally, most reports, including my own, give a negative history of epilepsy.

Fairlie[5] draws attention to the use of the Pinson bomb in a large percentage of the cases. In 11 of Pinson's 15,[6] and in one recorded by Dickson,[7] this was the method employed. Fairlie suggests that the bomb is the cause, possibly because of something inherent in its superheating of the ether.

Superheating is peculiar to this method, but since the convulsions may occur in the absence of the bomb the theory breaks down. In my own case an ordinary closed inhaler was used, and in some of the others the open method or Shipway's apparatus.

Fairlie[8] also suggests that high concentration of ether or excess of CO_2 is the cause, both of which, he thinks, are specially liable to occur with the bomb method.

But high concentration of ether and excess of CO_2 can also *be obtained by other methods with apparent impunity*. In the early years of the century ether was given exclusively in closed inhalers to patients who had received no preliminary medication whatever (the resulting cyanosis causing ether to be disliked by the surgeons of that generation) and convulsions did not occur. Extreme cyanosis is often seen during inexpert nitrous oxide administration, but it produces nothing more serious than the jactitations of the textbooks, which cease as soon as air or oxygen is given. Again, true ether convulsions are not ushered in by cyanosis.

Hewer[9] brings forward the additional argument that convulsions have occurred during endotracheal administration, when the CO_2 content of the alveolar air is less than normal. Pinson[10] blames high concentration of CO_2, while denying that the bomb is a factor in its production. The same objections apply as in the preceding paragraph.

Hornabrook[11] holds that ether is not to blame, but that the atropine given before anaesthesia is the cause, a dose safe enough in itself being an overdose to a patient under ether.

It is true that atropine in poisonous amounts will cause convulsions, but it is difficult to believe that routine doses can have this effect, when it is common knowledge that they are insufficient to produce the other manifestation of atropinism—pupillary dilatation. If they did, convulsions would be very common and the synergism would be well

known, in the same way that the dangers of chloroform combined with adrenaline are well known. Atropine was in use for years before convulsions were noted. Sington[12] remarks that at Great Ormond Street 1/100 grain is given to all children of 4 and upwards before every operation. Over 7,000 operations take place every year, and no convulsions have occurred. Most of the convulsions recorded are in young adults and the dose of atropine usually given is not greater than those mentioned above, which have been proved safe for children.

Gwathmey[13] puts forward an exactly opposite explanation. Referring to Wilson's paper,[12] he disagrees with the impurity theory and states that Wilson, in his post-mortem report, mentions the cause of death but overlooks it: "the lungs were congested and a small amount of frothy fluid exuded on pressure." Gwathmey found that in animals ether had no effect on the lungs after preliminary medication. In unmedicated controls the lungs were distended, congested, oedematous, and contained petechiae. Sometimes atelectasis and oedema of the alveoli and bronchi took place as well. This, he states, might cause the convulsions by diminishing the oxygen supply.

If this be true, ether convulsions should have been of frequent occurrence during the half-century before the introduction of preliminary medication, and should have declined to vanishing point as the practice became universal. The reverse is the case. They should also occur more frequently in out-patient and general practice, whereas all the reported cases seem to be in in-patients, who rarely escape the preliminary dope.

McDonagh's explanation[14] is original, complex, and comfortably dogmatic. ". . . Anaesthetic substances act by subjecting the protein particles in the plasma to sudden dehydration, and then to an equally sudden hydration. In the first process the protein particles go into solution, and in the second process they . . . tend to become precipitated in . . . the brain. It is to the protein particles becoming arrested in the cerebral vessels that the loss of consciousness is due. Should the hydration persist, or increase to a point where the surrounding nerve cells are damaged, then convulsions, coma, and death are liable to occur . . . It thus comes to pass that there is no fundamental difference between the convulsions occurring during anaesthesia and the convulsions . . . that are met with in . . . shock, eclampsia, status epilepticus, tetany, etc."

This is abstruse, and, I think, not free from discrepancies. If anaesthetic convulsions are identical in cause with eclamptic and epileptic fits why should anaesthetics be an infallible method of stopping these fits, as in fact they are? According to this theory anaesthesia should make them worse. Again, the theory does not explain why the hydrated protein particles should only have produced deleterious results during the last few years.

The late S. R. Wilson[15] attributed the convulsions to impurities in the ether, which must for historical reasons have recently arisen, due either to changes in the method or materials of manufacture or to modern methods of administration. His paper should be read by all interested in the subject. He concluded that the cases did not correspond to any known form of anaesthetic collapse, and that the safety of ether was seriously assailed. All the patients were young and most of them toxic. He recommended that only pure ether be used, and that it should be periodically tested and always stored away from light and air. Amber bottles and bone or ivory tubes should be used for Shipway's apparatus and stale ether discarded. All convulsions should be reported and the ether preserved.

The above precautions were all proved to be desirable by Wilson's experiments on the formation of peroxides and aldehydes in ether, but my own case, among others, demonstrates that impurities are not the sole cause. Aether puriss. (B.D.H.) was used from a stock bottle of amber glass wrapped in black paper, so that the action of light can be excluded. A clean closed inhaler was used, so there was no question of stale ether or the production of impurities by gaseous bubbling. The makers sent me an analysis of the batch of ether as marketed, which showed it to be pure, but, as many people had access to the anaesthetic room, it was quite possible that stale ether had been poured back into the bottle. The makers kindly analysed samples from this, and the results showed that no deterioration had taken place except for slight traces of mechanical dirt. Peroxide was less than 0.05 per million and aldehydes were absent. Wilson claims that these are toxic if present to the extent of 0.5 per cent.

Overdosage is suggested by Kirkby Thomas.[16] My own case was never very deeply anaesthetized. The patient was an easy subject and sufficiently relaxed when moderately under. I have had hundreds of patients far more deeply under without incident.

Hadfield[17] suggests some unrecognized impurity, but himself dismisses this theory because the suspected batches of ether have been used for many other patients without ill effects. The same writer[18] quotes an explanation from an unnamed source to account for the sudden outbreak in 1926. At the end of the war the Government sold large stocks of good ether, and manufacturers used them instead of making their own. As soon as these stocks were exhausted and ether manufacture was restarted convulsions began to be noticed.

Hadfield's inquiries as to the truth of this story were met with denials, as were my own. In any case the story collapses on examination. The Government ether was not a gift from the gods. Presumably it would come from the same sources as civilian ether, sources which would be working continuously before, during, and after the war. The army consumption was so enormous that the Government was very unlikely to accumulate sufficient stocks to last the whole country, including the Ministry of Pensions, for eight years. Even if this happened, as Hadfield pertinently remarks, "are we to believe that on resuming manufacture they all became so inefficient as to produce ether which caused symptoms never produced by even the worst ether during the previous seventy years?" Finally, in many cases, including my own, the ether was found to be pure.

Hadfield[19] suggests idiosyncrasy with a qualification. "Probably in all cases it is necessary for one or more of several other conditions to be present at the same time." Heat, sepsis, or other toxaemia, impurities in the ether, and youth in the patient are the other factors assumed to be necessary in addition to personal idiosyncrasy. He illustrates this by a case described as "some thyroid condition." Two operations took place, both attended by convulsions, the second time fatal. Here thyroid toxaemia was present on both occasions. One of Wilson's cases also fits this hypothesis. A patient had an anaesthetic for an open fracture with no ill effects. Three days later another for gas gangrene was accompanied by fatal convulsions. Here the accessory factor only came into play on the second occasion.

But, on the other hand, one of McDonald's cases,[20] a girl of 2, had slight non-fatal convulsions during an operation for cicatricial contracture of the fingers following burns. Two anaesthetics were given to her afterwards without any trouble, a fact which is inexplicable on the hypothesis of idiosyncrasy. It is interesting to note that this is one of the few non-septic cases on record, thus forming a double argument against the theory.

A case described by Bull[21] here crops up awkwardly. In 1919 (again an early date) he met with convulsions in an Arab woman at Basrah. The climate was too hot for ether, and chloroform was used.

This is a strong argument against all the theories which accuse the ether itself. In this case no oxygen was used (see below).

Mennell[22] suggests over-oxygenation. The eight cases which had come to his knowledge were all flooded with oxygen and deeply anaesthetized.

This may be considered in several different ways:

(*a*) Over-oxygenation pure and simple. As an example of the untoward effects of a normal and essential gas there is a condition known to deep-sea divers as oxygen intoxication, but here the gases are supplied under great pressure and the conditions are different. It is for the physiologists to find out whether convulsions can be produced by a mere excess of oxygen at normal pressure. It seems unlikely, because they form a feature of the second stage of asphyxia. My own case was supplied freely with oxygen.

(*b*) The production of impurities in the ether by the action of oxygen. The comparative unimportance of these has already been dealt with.

(*c*) The ability of the nerve cells to absorb more ether in the presence of oxygen. It is true that oxygen often helps to deepen the anaesthesia in a difficult case, but this effect is automatically limited by its sedative action on the respiratory centre. Also, as in my own case, the convulsions may occur when the patient is not excessively deeply anaesthetized.

(*d*) There is another possibility which has apparently been overlooked—impurities in the oxygen itself. In favour of this

tissue the musculature has been completely replaced by fibrous tissues, prolongations from which spread throughout its musculature. The fibrous tissue is well supplied with blood vessels of considerable size and there is no indication of a true sarcoma."

It is noticeable that the sections do not show any inflammatory process, but suggest rather the appearance of a neoplasm.

Endocrine disturbances have been described as a cause of myositis fibrosa progressiva, but probably some non-specific toxin of intestinal origin is an important factor.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CURIOUS COMPLICATION OF MEASLES AND WHOOPING-COUGH.

THERE has been for some time evidence of a changing character in our common infectious diseases and the complications arising. This has been noticeably so in cases in which measles and whooping-cough have occurred in conjunction. The case here recorded, however, presented features I have never encountered before.

A girl, aged 7 years, of poor physique, but previously healthy, developed a cough in March. A typical whoop came on two weeks later, and at the same time the child commenced a severe cold in the head, with a rise of temperature to 101°. As there was a considerable epidemic of measles also about, I warned the parents that an attack of this disease might be beginning. A typical rash developed on the morning of April 9th, and the progress of the case was as follows.

April 10th. Child very ill; temperature 103°; rash fully out; some headache, cough troublesome.

April 11th. Severe headache; temperature 103°–104°; rash fading on face.

April 12th. Pain in head intolerable; child delirious; became unconscious in the evening; temperature 104°; pulse 140.

April 13th. Child unconscious; in the morning she ceased to move her left leg, and by evening her left arm was also to all appearances paralysed. On the left side the knee-jerk was exaggerated, and ankle clonus was present. There was no definite Kernig's sign, and no tache cérébrale.

April 14th. Temperature 100°; pulse 110; child seemed slightly conscious, but appeared, to my horror, to be blind.

April 15th. Child conscious, but blind; can move left leg, but not arm; temperature 99°, pulse 100.

April 17th. Child can now move left arm very slightly and leg better. Complains of severe headache, but can distinguish between light and dark; can ask for the bedpan, and is sleeping for two or three hours at a stretch. The ankle clonus is gone, but the knee-jerk is still more marked than on the right side.

From this stage the child made a gradual recovery. The eyesight, after considerable photophobia, became normal in a fortnight. The leg first, and then the arm, entirely recovered. The girl is now (June 15th) perfectly normal; she is unusually bright mentally (which, incidentally, I had warned the parents might not be the case), and has had no ill health since.

Dr. Edmondson of Lancaster, who saw the patient with me, agreed that it was obviously a case of cerebral irritation, and suggested the possibility of the cause being a secondary rash on the meningeal membrane.

The treatment, on her return to consciousness, was simply urotropine, 5 grains every four hours.

Reports of Societies.

PSYCHIATRIC LESSONS FROM AMERICA.

AT the quarterly meeting of the Royal Medico-Psychological Association held at the House of the British Medical Association on May 22nd, with the president, Dr. NATHAN RAW, in the chair, a discussion took place on American psychiatry and its possible bearing on the application of recent local government and mental treatment legislation.

Dr. A. A. W. PETRIE, who opened the discussion, gave an account of a recent visit to American general and mental hospitals, psychiatric clinics, reception units, observation wards, and mental deficiency institutions, as well as to mental hygiene centres and various forms of child guidance organizations and associated nursery schools. Observations were also made of psychiatric work in connexion with juvenile courts. Each State, said Dr. Petrie, had its own method of dealing with the problems involved. In the progressive Eastern States it was usual for the mental hospital service to be a subsection of the state welfare services under medical commissioners. Concentration of executive authority in the State rendered progressive development easier, and made it more possible to obtain legislative and other changes. Well-organized State social services were being developed in New York and New England. The larger unit provided by a State allowed a co-ordination of activities that was not possible in smaller units. New York State, for instance, dealt with over 63,000 patients, who were drawn from a population of 44,000,000. The recent Local Government Amendment Act, however, did make one authority in an administrative area responsible for the treatment of the earliest stages of mental disorder. Well co-ordinated and efficient reception hospitals should take the place of the present wasteful division into observation wards of doubtful efficiency. Dr. Petrie also hoped that the Mental Treatment Bill when it became law would allow the development of voluntary clinics on the same lines as in the Maudsley Hospital and the famous Phipps Clinic in Baltimore, which consisted of sixty beds and an out-patient department, education and research being prominent features. Notable also was the clinic at Philadelphia, a hospital somewhat resembling Bethlem in London. The Psychiatric Institute which had been established in New York in connexion with the medical unit of Columbia University would be one of the most notable in the world when fully developed. Reception hospitals were increasing in number, which was one of the most hopeful signs in the United States. He doubted whether such clinics and reception hospitals should be an actual part of the hospital to which they were attached. The out-patient department at the Boston Psychopathic Hospital, which was the clearing house for Boston area, attracted as many patients as the corresponding out-patient department at Boston General Hospital. The work of these reception units was largely determined by the source of the admissions. In the Chicago clinic, with its 175 beds, about 100 beds had to be cleared weekly in order to deal with new admissions. These units had not usually sufficiently large staffs to deal with the great amount of material. A unit with 600 beds was projected in New York. The chronic patients in the large State hospitals in America were not any better dealt with, in Dr. Petrie's opinion, than they were in England; in America overcrowding occurred at many places. Much difference of opinion existed in America as to what was the best size of mental hospital. In Massachusetts, a very progressive State, 2,000 patients was the usual limit. He found in the United States a tendency, similar to that in England, to modernize old hospitals by building new and up-to-date units for recently admitted mental patients, and infirmary blocks for those suffering from physical diseases. He also saw good examples of the villa or colony hospital. Consultants were usually appointed on a liberal scale in American mental hospitals. In the progressive States the medical staff was in larger proportion to the number of patients than in England; in Massachusetts there was one assistant physician to 150 patients. A useful appointment, common in the States, was that of clinical director or clinical psychiatrist, who was equal in rank to the deputy medical superintendent and the pathologist. He directed and co-ordinated treatment, and was usually a teacher in a medical school.

The laboratory facilities were similar to those in England; frequently there was a more elaborate equipment. Lectures to psychological and theological students and social workers in general were encouraged in the States. Much could be done in this way to break down the prejudice and mystery which were generally associated with mental hospital work. A sharp division existed between nurses and attendants, based upon the preliminary education required. Attendants had no special training. The line of cleavage would become more marked in the future when a complete secondary education for nurses was demanded. Occupational therapy, said Dr. Petrie, was more broadly developed in a general way in the States than in this country. At St. Elizabeth's Hospital, Washington, sixteen occupational therapy officers were engaged

for 4,000 patients. The institutional farms tended to be larger than ever. Canning of meat was common as a form of occupation. Hydrotherapeutics was well organized, and hot baths and packs were usually employed, sometimes under conditions which in this country would be termed "restraint." Electrical treatment installations were generally of a high standard. Diathermy and other high-frequency apparatus was often used to induce high temperature in the treatment of general paralysis. Ultra-violet and infra-red light rays were very popular, and it was common to see automatic recording apparatus in connexion with bath treatment and blood pressure. Out-patient departments for mental cases were usually run in connexion with the State hospitals. This certainly kept the medical staff in touch with the early phases of the disease. The terms of commitment varied in the different States, but, on the whole, were not very different from those obtaining in England. Temporary observation was permitted for a period of from ten to thirty days. Several States permitted voluntary admission, but owing to the overcrowded condition of the mental hospitals few were received on this basis in the State hospitals. The cafeteria (self-service) system was worth consideration as there was a minimum of waste, but Dr. Petrie did not think that even the advantages of the system would justify the cost of initiating it in this country. An interesting development was the wide establishment of "beauty parlours" and hairdressers' shops in State hospitals, which did much to improve the appearance and increase the self-respect of the patients. Another feature was the combined canteen and club rooms provided for patients on parole. The cost per patient per week in the States averaged about 35s. In Canada it was rather less, in New York a little higher. Dr. Petrie was favourably impressed with the mental defective "schools" which he inspected at Wrentham and Letchworth. To a great extent the institutions trained their own people, as there were not many trained teachers available for the work. Child guidance, nursery schools, and parent guidance were comparatively new features; each of these agencies had a psychiatrist who acted as director. Sometimes a children's physician, a social worker, and a worker who specialized in recreation were added. This work had been started in association with juvenile delinquency. The mental hygiene movement had done much to stir up and educate public opinion in the North American continent. One reason why progress was being made was that the professions and laity in the States were being educated to take a more reasonable attitude towards mental illness.

Dr. J. R. LORD said his visit to the United States to attend the World's Mental Hygiene Congress was a short but intensive one. The medical profession in America was not so unanimous about the value of sterilization as was thought. The layman, however, had taken up the subject keenly. An important discussion took place at the congress on the organization of the mental hospital in the mental hygiene service. He had expressed the view that if care were not taken there was a danger that psychiatry might again become a closed system and revert to a position of isolation. There should rather be a psychiatrization of all medical and social services, leaving to psychiatry the care and treatment of actual mental disorders from their earliest stages. The magnitude of the problem of the mentally afflicted in the United States was much greater than in England. The rate per 100,000 of the general population in America for first admissions to mental institutions of all kinds was 76.0; in England and Wales it was 45.4. In America 277.7 per 100,000 of the population were in mental institutions; the figure for this country was 290.6. To the American figure, for comparative purposes, must be added 24.0 for paroled cases, giving a total figure for that country of 301.4. In addition, American State institutions were for the most part shockingly overcrowded. State control of mental institutions had been commented upon favourably, but Dr. Lord could not help thinking that such a state of affairs would not have been tolerated if the responsibility for providing the accommodation had rested with local authorities. The more closely local people were identified with the care and treatment of their mentally afflicted and defective, the sooner would ignorance and prejudice regarding them disappear, and the need for judicial intervention be reduced to minimum requirements. It was for the State to lay down large principles and advise how they should be carried out, reserving to itself a veto when such principles were disregarded. What appeared to be certain was that America had no intention of trying to solve its psychiatric problems by bricks and mortar alone, and that was the lesson America had for this country. Child guidance and welfare work of all kinds directed towards and organized for the prevention and early treatment of mental disorders, eugenic measures, and parental education were to have the financial assistance of the State for the future—hence the reluctance to increase the State hospital accommodation. America had also lessons for us in the importance it attached to the psychiatric education of medical men, social workers, occupational therapists, and others in the field of public welfare. Research work, too, was more widely developed and received greater support and encouragement from both the State and private citizens than in this country. As regards the mental services, Dr. Lord said that America had little or nothing to teach this country—certainly not if the Mental Treatment Bill became law—except perhaps in respect of recent enactments in one or two of the more progressive States, and also in the way in which patients were allowed out on leave or discharged.

OCCUPATIONAL DERMATITIS AND CHEIROPOMPHOLYX.

AT a meeting of the Section of Industrial Hygiene of the Royal Institute of Public Health, on June 5th, a paper on occupational dermatitis and cheiropompholyx was read by Dr. W. J. O'DONOVAN, physician to the skin department of the London Hospital.

Dr. O'Donovan described cheiropompholyx as a deep vesicular and bullous eruption of the extremities, more commonly of the hands, characterized by great itching, recurrences, and seasonal exacerbations, particularly in May and June. This disease was a pattern reaction in individuals with a predisposition to the eruption owing to chance or heredity. It appeared after exposure to circulating toxins and drugs, after virus infections, and exogenic skin damage; it was often seen after nervous strain such as worry and shock, and was continued by the strain of too intimate acquaintance with county court procedures under the Workmen's Compensation Act. Cheiropompholyx was not a disease *sui generis*, but belonged to a group of skin affections in which the effects of mental strain and instability of the nervous system were commonly accepted by teaching dermatologists. If looked for in the same cases, other skin maladies were frequently found: chronic urticaria, pruritus ani, "névrodermite" (the lichen simplex chronicus circumscriptus of Vidal); a chilblain type of circulation and exophthalmic goitre might be discovered, either actually present or in the patient's past history. Admittedly, cheiropompholyx was often found in occupations having a recognized skin hazard, but it occurred in many other trades. It was most commonly exhibited by furriers and cleaners, less frequently by nurses, medical students, sugar workers, and bakers. It was found also in workers on the "dole," in childless women at home, and sometimes in children of school age. Moreover, after first occurring at work and relapsing after a resumption of the same work, further long relapses would occur at any work, after exercise, and even under observation in a hospital bed. Red, scaling, and moist dermatitis of the hands had often a definite history of a distinct cheiropompholyx origin. It was most difficult to believe that a surface damage to the skin arising in the course of work tolerable to most persons should be followed by a deep disorder of the basal layer of cells found in active form six or more years afterwards when the original cells affected had long been shed; surgical incisions, electrical burns, and acid splashes had no such influence on the skin for a decade afterwards. It was hard to trace a parallel between the damage done by

flour and sugar and the admittedly persistent ill effects of penetrating radio-therapeutic dermatitis. Dr. O'Donovan stressed the great pressure exercised upon insurance and works doctors to certify a dermatitis of the hands as due to work.

The condition of cheiropompholyx could not necessarily be diagnosed at sight; epiphenomena due to scratching, sepsis, or the application of strong antiseptic remedies made photographic recognition a wrong technique. The taking of a full history was essential; the patient should be allowed to talk, to reveal dramatic introspection, and to use superlative adjectives (" terrible " pain, " unbearable " irritation, etc.), associated with a placid mien, a comfortable girth, and trifling physical signs. Charcot's full range of hysterical stigmata could often be demonstrated even in a public clinic. Dr. O'Donovan urged clinicians to be as rigid in their acceptance of occupational skin disease as were laboratory workers in admitting the coercive nature of any demonstration. Coincidence, intervening and primary causes, and transient aggravation due to work in general or to a specific irritant, should be recorded with some precision. If after full consideration the doctor was uncertain, he should refuse to facilitate book-keeping or doubtful claims at the expense of scientific certainty; his modest opinion should be clearly qualified to distinguish it from a dogmatic statement of fact. The irrevocable nature of the certificates of many certifying factory surgeons led to much injustice, since time often upset the confident opinion. The semi-permanent pensioning of sufferers from minor skin affections conduced after a time to obvious deterioration of the patient's morale. Neuroses were becoming more common in every field of medical practice, and not least in dermatology. The occurrence of compensated cheiropompholyx in work as bland as the sewing of curtains and the stitching of georgette blouses compelled the dermatologist to halt in the easy acceptance of work as the satisfactory causal factor. A predestined fragility of the integument, which might erupt under many factors of external and internal strain, was a more probable explanation of much cheiropompholyx and its later eczematous developments. The notes of a case should be sufficiently complete (comprising the factors of personality and environment as well as of occupation) to stand cross-examination upon these matters before a hand dermatitis having a spontaneous history of irritating, pinhead, watery blisters between the fingers was accepted as a case of occupational dermatitis.

REDUPLICATION OF RENAL PELVIS.

A MEETING of the Section of Surgery of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on May 16th, with the president, Mr. R. ATKINSON STONEY, in the chair.

Mr. T. J. MORRIN showed a specimen of reduplication of the renal pelvis and ureter. *The patient, a female* aged 35 years, was admitted to hospital complaining of pain in the right renal region, with rigors, vomiting, and dysuria. Her symptoms started three years previously, when she was under the care of a genito-urinary specialist. The double ureters were recognized, and sympathectomy was performed on the renal pedicle. She remained free from symptoms for two and a half years, and then began to have them more severely than before. A pyelogram was taken of the upper ureter. Owing to the position of the lower ureter, behind a ridge of mucous membrane, the lower opening could not be catheterized. The specimens obtained from both kidneys were normal, but the bladder specimen showed a few leucocytes and red cells, and an occasional cast. Operation by the anterior extraperitoneal route was adopted to avoid the scar of the previous lumbar operation. Beyond the two ureters no gross deviation from the normal was noticed. In view, however, of the persistence of symptoms, nephrectomy was carried out. The specimen showed complete duplication of the kidney, pelvis, and ureter. The lower ureter emerged from the upper segment of the pelvis, thus preventing adequate drainage, and producing hydronephrosis. This hydronephrosis was completely intrarenal, there being no extrarenal pelvic dilatation.

The PRESIDENT, taking into account the appearance of the specimen, asked if it might have been possible to remove only the lower half of the kidney. He supposed there had been no way of injecting the extra ureter. Mr. V. J. MCALLISTER said that as a rule in pelvic reduplication the lower portion of the pelvis was the larger. It would be an advantage if a method could be worked out for showing by means of a pyelogram whether there was reduplication of the pelvis or not. Mr. F. J. HENRY suggested that if the ureter coming from the dilated pelvis had been merely ligatured, the other pole would have been saved, and thus renal tissue have been conserved. Mr. MORRIN, in reply, said that the difficulty about doing a partial resection was to arrive at a diagnosis beforehand.

Fibroma in the Knee-joint.

Sir WILLIAM WHEELER showed an illustration of a loose body (fibroma) found in the knee-joint of a male, aged 25. The case was of interest owing to its rarity. So far as could be ascertained, it was the result of neither disease nor injury. At the time of removal it was believed to be a lipoma, but on microscopic section was found to be a pure fibroma. The patient sought advice owing more to discomfort and stiffness than to actual pain. There was no effusion, and no history of trauma. The only point which might have a bearing on etiology was that the patient was a conductor of a band, and kept time by constant movements of the knee-joint. A localized movable swelling could be felt to the inner side of the patella. Movements of the knee-joint were not limited, but full flexion and pressure on the swelling caused discomfort almost amounting to pain. X-ray photographs were negative. A provisional diagnosis of a cystic condition of the internal semilunar cartilage was made. The knee-joint was opened, and what appeared to be a lipomatous mass extruded. It was attached by a fine pedicle to the outer side of the deep surface of the ligamentum patellae. The pedicle was believed to spring from the retropatellar pad of fat, but may have been from the synovial membrane. After removal of the body the knee-joint appeared normal in every respect.

Calcification of Kidney.

Sir William Wheeler also recorded the case of a patient, aged 68, who had served in France for two years. He was invalided home in 1918, owing to frequency and pain on micturition. During the last few years he had intermittent attacks of high temperature, with recurrence of the bladder symptoms. On cystoscopic examination the bladder was found tolerant, and held a normal amount of fluid. The orifice of the right ureter could not be seen. On the left side it was normal in appearance, and normal urine was excreted. Indigo-carmine was eliminated in six minutes. There was some congestion of the trigone and fibrosis about the neck of the bladder and prostate. The history sheets stated that tubercle bacilli were never found in the urine, and that guinea-pig inoculations were negative. An *x*-ray photograph showed complete calcification of the right kidney. The ureter appeared to be palpable. Sir William recorded a similar case of a pensioner seen some years ago, but the kidney was not completely calcified. There was pain and frequency of micturition. Several attempts had been made to remove the kidney, but the operation was abandoned owing to adhesions and haemorrhage. The patient was cured by division and ligature of the ureter about its middle.

Mr. V. J. MCALLISTER said that radiological examination in these cases was a great help, because often the bladder was extremely irritable, and it was difficult to see the openings of the ureters. In this case *x* rays had shown that the kidney was completely destroyed. Mr. F. J. HENRY said that he found it rather difficult to accept the view that calcification was due to tuberculosis. The general outline of the kidney shadow did not suggest a tuberculous origin, the calcification being a good deal too uniform and not sufficiently patchy. He asked if there had been any calcification of the tibial arteries. Sir WILLIAM WHEELER, in replying, said that the arteries of the limbs had been *x*-rayed, and there was no general calcification; in fact, there was no arterio-sclerosis.

Reviews.

INTRACRANIAL PRESSURE.

The Intracranial Pressure in Health and Disease,[1] a symposium issued by the Association for Research in Nervous and Mental Disease, includes contributions from most of the American physiologists, neurologists, and neuro-surgeons who have gained distinction in recent years for their work on intracranial conditions. The importance of work on intracranial pressure at the present time cannot be magnified. Doubtless as a result of the steady development of neurological surgery, the problems of intracranial pressure have been studied during the last twenty years with unexampled activity, and already, in a remarkably short time, clinical medicine has gained from this work such aids to diagnosis and treatment as Queckenstedt's test, ventriculography, and the use of hypertonic salt in the treatment of raised intracranial pressure.

The first section of this book is concerned with the physiology of intracranial pressure, and in it such workers as Weed and Howe set out their views on the phenomena of intracranial pressure, and report their most recent experiments. It is interesting to note that there is some divergence of opinion as to whether the cerebro-spinal fluid is absorbed by the arachnoid granulations or by the capillaries of the brain, or by both. Many interesting experiments are recounted that show how intracranial pressure is modified by venous pressure, by posture, and by the administration of hypertonic and hypotonic solutions. The work is excellently described and illustrated, and it raises fresh possibilities in the treatment of intracranial conditions, as, for example, in the treatment of meningitis suggested by Kubie. But the reader is left with a sense of disappointment that so little attempt is made to link up the experimental observations with phenomena observed in various stages of intracranial disorders in man. He appreciates the more, therefore, some important observations by Stevenson, Christensen, and Wortis on cerebral hernias in man, which show that the intracranial pressure is raised during sleep and by the administration of morphine. When caffeine is given there is a fall of intracranial pressure, and consequently the authors advocate caffeine as the sedative of choice when intracranial pressure is raised.

The second section deals mainly with the methods of measuring and estimating rise of intracranial pressure in man, and is chiefly remarkable as showing the wide uses of the exploring needle in clinical investigations in the United States at the present day. Lumbar puncture, cisternal puncture, and ventricular puncture are used, either alone or in combination, for the diagnosis of intracranial conditions, and the pressure is measured before the cerebro-spinal fluid is withdrawn. Munro finds that after birth injury the pressure of cerebro-spinal fluid in newly born infants is raised, and he advocates its reduction by lumbar puncture and withdrawal of fluid. In hydrocephalic infants Blackfan and his associates are often able to ascertain the type of hydrocephalus by combined ventricular and lumbar puncture. The same type of combined puncture has been investigated by Ayer, and also by Hodgson, as a method of diagnosing intracranial tumours. In subtentorial tumours, and especially in tumours of the cerebello-pontine angle, the protein content of the spinal fluid is much higher than that of the ventricular fluid. Ayer, however, doubts whether this method is worth the risk of doing a lumbar puncture, since the findings are not pathognomonic of intracranial tumour. In the light of this statement by one who is noted for his pioneer work on cisternal puncture, the claim of Masson, another contributor to this volume, that lumbar puncture in intracranial tumour is never dangerous if certain precautions are taken is perhaps unduly optimistic.

The ophthalmic aspects of intracranial pressure are not neglected. Parker reports further work in support of his earlier contention that, other things being equal, papilloedema tends to appear first in the eye of lower tension. The method of Baillart and Magitot of measuring pressure in the retinal arteries is examined by several workers. From perusal of their papers the reader will probably form the opinion that the method is difficult to employ with even approximate accuracy. And from other experimental work in this volume it is very doubtful whether retinal arterial pressure is appreciably raised when the intracranial pressure rises. It does not seem likely, therefore, that the method will become of practical value in estimating rises of intracranial pressure. Horrax and Haight study the recession of papilloedema after operations for brain tumour in Cushing's clinic. The morbid anatomy of raised intracranial pressure is dealt with by Hassin, and, in a particularly thoughtful paper, by Wilder Penfield.

The remaining two sections of the book consist of papers from a number of neuro-surgeons on the clinical and therapeutic aspects of intracranial tumours. These sections are rather disappointing, since no attempt is made to attack the problem of distinguishing, in cases of intracranial tumour, between those symptoms and signs that are a result of a general rise of intracranial pressure and those that are produced by disturbance in the region of the tumour itself. However, there is an interesting article by Dandy on tumours of the third ventricle, in which the author describes his methods of localizing the tumour by ventriculography, at a time when there are no distinctive localizing signs, but when it may be still possible to remove the tumour. Dandy states that he has two patients alive, one five years and the other two years after removal of a tumour of the third ventricle. It is to be regretted that the cases are not reported in detail, for this is obviously pioneer work of the first order, and other surgeons who are confronted with cases of this type would be greatly helped by a careful and full report of Dr. Dandy's experiences. Another outstanding article in this part of the book is a critical and commendably impartial examination by Professor Heuer of the effects of subtentorial and subtemporal decompressions in his own series of some eight hundred intracranial tumours. His experience is that decompressive operations are of no value in tumours of the brain stem and cerebello-pontine angle, whereas in tumours of the cerebellum and of the cerebral hemispheres an appropriately placed decompression may be expected to relieve pressure symptoms in at least 75 per cent. of the patients who survive the operation. There will doubtless be many who do not agree with all of these conclusions, and it is to be hoped that this paper will stimulate other neurological surgeons of experience to make a similar examination of their material.

The publication of such a book is particularly opportune, for it appears at a time when the problems with which it deals are being studied from so many different aspects, and by means of so many technical procedures, that there is danger that workers in one field may be unaware of what is going on in other fields of the subject. This book succeeds in giving a comprehensive survey, and we have no hesitation, therefore, in recommending it to all who are interested in the subject of intracranial pressure.

TREATMENT OF LARYNGEAL CANCER.

THE treatment of cancer in regions accessible to radiation is now engaging general attention, so that Dr. MARCEL OMBRÉDANNE's work on the treatment of endolaryngeal cancer[2] appears at an opportune moment. It is further welcome because it contains an authorized account of the work of Dr. A. Hautant, written by one of his pupils. In the first part Dr. Ombrédanne passes in review what has been accomplished by surgery from the time of Billroth, and gives an unbiased description of what can now be done by thyrotomy, hemilaryngectomy, *laryngectomie économique*, and total laryngectomy. While the larynx is not a vital necessity to its possessor, its functions are such that he

[2] *Traitement du Cancer Endolaryngé: L'Hémilaryngectomie (Technique A. Hautant)*. Par Dr. Marcel Ombrédanne. Préface du Dr. A. Hautant. Paris: Masson et Cie. 1930. (Med. 8vo, pp. 174; 22 figures. 25 fr.)

can ill afford its total loss, and thus conservative operations, provided they are adequate to their purpose, are of prime importance, and much ingenuity has been exercised in devising them. It is natural, then, that the author should pass on to consider the achievements of radiation, a still more conservative method of treatment. Dr. Hautant has been a pioneer in the use of radiation, with the collaboration of Professor Regaud and Dr. Coutard at the Institut Curie. The possibility of obtaining permanent benefit by means of x rays has been amply demonstrated, but an experience of some two hundred cases has shown that those benefiting constantly fall within two limited classes. First, the glandular cancers which arise in the ventricle or on the ventricular band; these are rare, and do not amount to more than one-tenth of the cases. Secondly, cancers limited to one cord which is still mobile. It follows that in most cases, unless x rays are combined with surgery —a method which has given some success—surgery is still the principal weapon.

The chief success of radium has also been in early cases, with the growth limited to a movable cord; in other words, it is just in those cases for which a conservative operation such as thyrotomy is inadequate that radiation also is uncertain and unreliable. Dr. Hautant has therefore turned his attention to devising a radical operation adequate to deal with more advanced cases without inflicting the mutilation of laryngectomy, and the second part of the book describes this operation and the principles on which it is based. It is called hemilaryngectomy, but is not strictly so, and differs from the true hemilaryngectomy of Gluck. It is similar to laryngo-fissure as now practised by Sir StClair Thomson; but it is still more extensive, for part of the cricoid cartilage is removed, giving a wider access to the subglottic region. The results show that this operation has been practised with success in cases too advanced for the widest excision by laryngo-fissure, but it has only given 40 per cent. of good results in the group of advanced cases which would otherwise have called for total laryngectomy. Dr. Hautant has made notable contributions to the treatment of laryngeal cancer, both by radiation and by surgery, but it appears that the search for a satisfactory alternative still fails in most of those cases in which an alternative to laryngectomy is most needed to preserve some part of the laryngeal functions.

The book is written with extreme lucidity, the steps of the operation are beautifully illustrated, and there is a valuable bibliography of writings on laryngeal cancer since the year 1900. It is an important addition to the literature of laryngeal surgery.

ELECTRO-DIAGNOSIS OF NERVOUS DISEASES.

IN disease of the nervous system a knowledge of the electrical reactions of the excitable tissues is often of diagnostic importance. At the present time the faradic and galvanic currents are almost universally employed for the determination of these reactions, although the defects of the customary methods have long been realized. In recent years important researches have been conducted by French workers. The studies of Professor Lapicque and Dr. Bourguignon, and the determination of the "chronaxie" of muscle and nerve, in health and disease, may lead to the discovery of information of diagnostic or prognostic value. In an excellent monograph entitled *L'Electro-diagnostic*,[3] Dr. P. DUHEM gives a clear and concise account of the use of electrical methods in the investigation of diseases of the nervous system. He describes all that is of importance in what he calls the "classical methods" of investigating the electrical reactions. In these methods the faradic and galvanic currents are employed, but the procedure, while quick and convenient, is not free from possibility of error, nor is it as precise as could be desired. The author then gives an account of the methods which have been devised in order to overcome these disadvantages. Most important of these is the method in which the chronaxie is determined. The chronaxie is a measure of the duration of the excitatory process. In normal muscle and nerve it is extremely brief, but in denervated muscle it is from twenty to one hundred times longer. The determination of the chronaxie has not yet provided information of clinical importance that the customary method of electrical testing does not afford; but it is a much more accurate and precise method of examination, and it is quite likely in the future to aid diagnosis and prognosis in disease of the nervous system. Bourguignon has made the interesting observation that when muscles on one side of the body show the reaction of degeneration the corresponding muscles on the opposite side, though clinically normal, show a lengthening of the chronaxie.

Dr. Duhem concludes with a description of the electrical reactions that are found in different diseases of the nervous system. The book is written in a lucid manner, and is a credit to the French school, which, from the days of Duchenne onwards, has made such important and original contributions to the subject of electro-diagnosis.

THE MORPHINE HABIT.

IN the introduction to his well-written little book on *The Morphine Habit*[4] Dr. G. LAUGHTON SCOTT protests against the popular view that vicious weaklings form a considerable part of the addicts in this country. On the contrary, he shows from his own experience that a number of doctors have successfully conducted large practices for many years while taking a constant amount of the drug throughout the whole period. So far from the addict getting any voluptuous satisfaction from the drug, except in the earliest stage, the morphine habit is an intimate physical necessity from which the victim is usually trying to escape. From his experience of English addicts, the author is of opinion that overwork and fatigue are the principal causes of the habit, while calculated self-indulgence is probably the least common of all motives. More than half of his patients have been persons of apparently sound nervous inheritance, about a quarter presented a definite though slight psychical abnormality, while not more than 15 per cent. showed a general failure of adaptation to the difficulties and responsibilities of life.

Dr. Laughton Scott has devised a system of withdrawal by which he claims that in almost every case the discomfort and shock may be reduced to a minimum without producing either delirium or coma. The procedure, which is a modification of Lambert's method, consists in a gradual withdrawal of morphine under a gradually developed tolerance to belladonna and hyoscine, with free and increasing use of luminal. Care is taken to reduce the morphine *pari passu* with the gradual development of belladonna tolerance so that the mental equilibrium is not disturbed. Numerous illustrative cases are recorded, several of which occurred in middle-aged medical men, while an appendix contains the experience of a medical morphinist who developed the habit as the result of being treated for iritis with injections of morphine by a physician who was himself a morphomaniac.

The work will be read with interest by every practitioner, who will gather from its perusal that not only is the morphine habit more prevalent than is generally supposed, and by no means confined to the degenerate and vicious, but that withdrawal of the drug is a simpler and more hopeful task than current teaching indicates.

DIFFERENTIAL DIAGNOSIS OF ALIMENTARY DISEASE.

THE comprehensive and ambitious series of handbooks on practical differential diagnosis, under the general editorship of Professor HONIGMANN of Giessen, has several times been noticed in these columns. The most recent of the series is Part 4 of the first group,[5] and is devoted to disorders of

[4] *The Morphine Habit and its Painless Treatment.* By G. Laughton Scott, M.R.C.S. London: H. K. Lewis and Co., Ltd. 1930. (Cr. 8vo, pp. vii + 94. 5s. net.)

[5] [illegible] Herausgegeben von Professor Dr. G[illegible] Medizin; Teil 4, *Erkrankungen der* D[illegible] Dr. Louis R. Grote. Dresden und L[illegible] 214-330; 5 figures. R.M.6.80.)

the alimentary tract, the author being Professor GROTE of Dresden. This little volume is similar to the remainder of the series, being a self-contained set of essays in somewhat dull and difficult prose on such topics as abdominal pain, dyschezia, examination of the faeces, and meteorism. It forms part of the group entitled "Internal medicine," and must be read in conjunction with its companion volumes. Those interested in the more recondite aspects of the functional and common disorders of the alimentary tract would do well to read through this book and the associated Parts 2, 3, and 5.

NOTES ON BOOKS.

In *Medicine. Its Contribution to Civilization*[6] Lieut.-Colonel EDWARD B. VEDDER of the Medical Corps, U.S. Army, sets out to present for the intelligent lay reader a non-technical account of the more important facts of preventive medicine. While, however, it is doubtful if many members of the lay public will be drawn to a work which describes in an unsensational way the advances that have been made in the medical sciences during recent years, medical men will find in it a great deal that is readable and useful. The book might, in fact, serve well as a textbook to be read, side by side with more formal works, by students working for the diploma in public health. In all his teaching the author displays an admirable common sense; thus, he points out that to open all windows in the dead of winter and spend all night shivering in bed is not to promote ventilation—the aim of which is to maintain the body temperature at the correct level—but to chill the body and so reduce its resistance to colds and other respiratory infections. And with regard to exercise and physical culture, he warns men of 40 and over against the dangers of excess, suggesting as a good working rule that exercise has been too severe if it is followed by fatigue that survives even a night's rest. His chapter on nutrition is up to date, and he emphasizes the need of including a sufficient amount of inorganic salts in the dietary, for the ordinary diet does not necessarily protect against inorganic deficiency. Whether he is explaining scientific phenomena in simple non-technical language, or writing about infectious diseases, nutrition, endocrine disturbances, the cancer problem, or the conquest of disease, Colonel Vedder is always clear in his exposition, and never fails, where it is appropriate, to enliven his text with pleasant humour.

The first volume of the fortieth series of *International Clinics*[7] contains as usual numerous papers on a great variety of subjects, among which we may draw attention to those by Professor Lewellys Barker of Baltimore on the diagnosis and treatment of the maladies grouped under the designation "sciatica"; further experiences with encephalography, by Professor Friedmann of New York; on hernia of the diaphragm, by Dr. P. E. Truesdale of Fall River, Massachusetts; by Dr. George F. Dick, on scarlet fever, with a consideration of other haemolytic streptococcus infections; and by Dr. Frederick Tilney, on the structural basis of behaviourism. Recent advances in toxicology are discussed by Dr. Max Trumper of Philadelphia, and recent advances in surgery by Dr. Donald C. Balfour and Dr. Archibald H. McIndoe of the Mayo Clinic. The volume concludes with a richly documented paper by Dr. Russell M. Wilder of the University of Chicago on the recently discovered endocrine diseases—hyperepinephrinism, hyperinsulinism, and hyperparathyroidism.

Many epidemiologists of ancient and modern times have surmised that cosmic or terrestrial forces are responsible for the disturbance of epidemiological equilibrium which finds expression in a pandemic of influenza. Dr. JOHS. MYGGE has devoted a well-documented monograph[8] to the subject and has himself made a number of observations. He has come to the conclusion that variations of the electrical state of the atmosphere, particularly oscillations of the manner of electrical exchange between the air and the earth with regard to convection charges, play some part in the genesis of an epidemic constitution. Dr. Mygge has assembled many data, but their interpretation requires technical knowledge of physical meteorology few epidemiologists possess, so that his work is hardly within the range of most medical readers. It should, however, be carefully studied by the fortunate few who have the needed preliminary knowledge.

In her little work on *Fevers and Fever Nursing*,[9] Miss EVELYN C. PEARCE, now sister tutor at the Middlesex Hospital, and formerly sister tutor at the Fazakerley Fever Hospital, Liverpool, has given a clear and practical account of the principal acute infections, including influenza, lobar pneumonia, puerperal fever, and venereal diseases, in addition to those usually nursed in isolation hospitals. There are an unusually large number of verbal errors, such as flagellae (p. 1), consular for proconsular (p. 73), Shick (pp. 82 and 203), rothelin for röteln (pp. 131 and 202), Frankel (p. 153), Schaudin and Hofman (p. 191), Wasserman (pp. 192 and 194), and neokharvisan (p. 194).

Four Months' Camping in the Himalayas,[10] by Dr. W. VAN DER SLEEN, is an interesting and well-written account of a tour in the valley of the Sutlej, following the comparatively unexplored main road from Hindustan to Tibet, which runs through that valley. The main object of the author was to study the geological formation of the valley, but the present volume is restricted to matters of general interest. A vivid description is given of the scenery of the entire route from Simla to Kunmarsain, including an account of some of the sacred mountains of the Hindus, and it is illustrated with numerous fine photographs. Of special interest are the descriptions of the manners and customs of the natives. Particularly worthy of mention are the accounts of the ceremonial of the dance of the gods, and of the funeral of the maharanee; these are illustrated by a number of photographs exhibiting the successive stages of the ceremonies and giving a very complete idea of the proceedings.

PREPARATIONS AND APPLIANCES.

A RADON SEED DEPOSITOR.

MR. W. ETHERINGTON WILSON, F.R.C.S. (Torquay), writes: The idea of this design is to overcome the rather slow and tiresome business of loading the gun each time with one seed; only one rod, P, is used, and need not be taken out of the instrument at all, as is done in other models.

Description of Parts.—The magazine M is lined with 2 mm. of lead, and will hold about fifteen 0.5 cm. or eight 1 cm. radon seeds. The magazine is loaded by ramming home piston rod P, which closes the opening of M into the open breech H, and introducing seeds at the lower end of the magazine. The ejector rod E is then screwed in until it meets the last seed. Having introduced the barrel B (ruled at 1 cm. intervals up to 10 cm.) into the tissues, the rod P is pulled back until it is clear of the breech H. A slight turn of the rod E, which is

a spiral, pushes up the column of seeds, and, *under direct vision*, one seed is seen to appear and lie in the breech; rod P then pushes it on and out of the barrel B. This process can be repeated in quick succession and the magazine emptied. The ring, finger, and thumb-grips R R R facilitate the use and steadying of the whole instrument; S is a sliding sleeve, which may be fixed at any point along the ruled barrel B. The rod P is bevelled slightly at its distal end, and acts both as a needle and a pusher quite effectively.

The instrument is heavy, simple, effective, and saves time. I would draw attention to two points: the breech is left open above deliberately to enable the operator to see one seed properly and safely introduced; it is absolutely necessary to allow one seed only to lie in the breech (the oncoming seed, if pushed too far by the fine adjustment rod E, will foul the rod P when it is pushed home). The knack is easily acquired.

Allen and Hanburys Ltd. of Wigmore Street, W., have made the instrument for me.

"HAZELINE" SNOW.

Messrs. Burroughs Wellcome and Co. (Snow Hill Buildings, London, E.C.1) have added a collapsible tube packing of "Hazeline" Snow to their well-known series of "Hazeline" preparations for the skin and mucous membranes.

ASTHMA RESEARCH.

A SCIENTIFIC meeting of the Medical Advisory Committee of the Asthma Research Council was held on June 5th, Dr. A. F. HURST presiding, when several workers on the subject gave an account of recent investigations.

Physiological Aspects of Asthma.

Professor R. J. S. MCDOWALL (King's College) said that from the physiological point of view asthma must be looked upon as essentially a symptom which indicated bronchial constriction with probably some turgescence. Constriction might be brought about by local irritation or by chemical, nervous, or psychic stimulus. It was highly desirable that the general metabolism of individuals suffering from asthma should be studied. The work of Oriel seemed to him very important in that connexion. It pointed to something wrong with the protein metabolism, due either to upset of digestion or to access of fractions of foreign proteins into the blood. He pointed out how many divergent views of asthma fitted into a simple picture. Asthma research was a much more coherent effort than at first sight seemed possible. The greatest need was to find out more exactly the nature and mode of production of sensitization.

The Hereditary Influence in Asthma.

Dr. G. BRAY (Asthma Research Clinic, Hospital for Sick Children), speaking from a study of hundreds of children, had found a hereditary factor in two out of every three children with asthma. The heredity was rather a history of allergy than of asthma alone; parents might have suffered from urticaria or migraine, and they had children with asthma. Of the 70 per cent. of children with an allergic heredity, rather less than one-third belonged to families where both parents were affected. Among the children at his clinic the asthma sufferers included three times as many males as females, but other investigators had found that from puberty onwards to the menopause a greater percentage of females were affected. Males, therefore, seemed to improve from puberty. Symptoms of asthma developed during the first year of life in 20 per cent. of the children, irrespective of a history of allergy in the parents. Those with a bilateral history all developed their asthma before the age of 10. It was stated in America that the earlier in life a person became sensitive the more pronounced was hereditary influence, but that was not borne out by his own figures. Up to the age of 2, food reactions were common; later on such things as feathers and hair played a more important part in etiology. With a pure asthma lineage a child was more likely to be affected with asthma; if there was a hay fever lineage, he was likely to have hay fever as well as asthma.

Dr. HURST said that the study of heredity offered some hope of prophylaxis. If as many as 70 per cent. of the cases had a history which pointed to heredity, the great thing was to get at the child asthmatics early, and find out by periodical examinations what could be done to prevent development of asthma. In his experience, in a family of half a dozen children it was very uncommon for more than one or two to be subject to asthmatic attacks. Dr. JOHN FREEMAN said that the weight of the heredity factor appeared to depend on the number of relatives. If there were few relatives there was a small chance of heredity becoming manifest. He thought a false division had been made by Dr. Bray between asthma due to heredity and asthma due to tissue damage; in his view these were not mutually exclusive.

Types and Age Variations.

Mr. FRANK COKE spoke on the necessity of recognizing types of asthma, for asthma was merely the *name* of a symptom. It was hopeless to lay down a line of treatment unless it was known to *which* type of asthma the case belonged. There was no panacea for asthma, and if a cure were found for cases of one type, so long as asthma was undifferentiated the cure would be applied indiscriminately in all types, and, because of its failure in all except the type to which it was appropriate, would be discredited. Thousands of cases has been treated with glucose, and the fact that it had not done good in many cases had prevented its application in cases which it might have benefited. The speaker drew attention to four types of asthma, all absolutely different: (1) cases in which the asthma supervened directly upon some upset in the chest, such as bronchitis; (2) ordinary cat or horse asthma; (3) a type of asthma seen, almost without exception, in plump women in middle life, probably suffering also from urticaria, with menstrual flow nearly always scanty, and a considerable amount of pain; (4) the aspirin-sensitive type, in which 5 grains of aspirin would throw the patient into paroxysmal asthma; these last cases had polypi in the nose.

Dr. L. J. WITTS (Asthma Research Clinic, Guy's Hospital) discussed age variations. The allergic diseases tended to occur early in life. Eczema, in nearly 90 per cent. of the cases investigated at Guy's, began before the age of 5; asthma before the age of 10; hay fever commonly before puberty, while urticaria was not so closely related to age, and might begin at any time of life. When asthma began before the age of 10, over 60 per cent. had some other allergic symptom as well. Skin reaction was almost a function of age, very frequent in early life, and diminishing later. In children asthma was a much more general disturbance than in adults. Very often in children dyspnoea was not the most common symptom. Children had headache, vomiting, sometimes bowel disturbance, but were well between attacks; later in life the patient was rarely free from dyspnoea. Up to 20 years of age the length of the attack might vary from twenty-four hours to seven days; in later life the attacks were much more brief—from two to four hours. The treatment of which he had had most experience was glucose, and in children under 10 there was a high percentage of improvement; in later life the response to glucose was poor.

Dr. HURST stressed the dangers of making too rigid a classification. It had been supposed that some cases were due solely to polypi in the nose, but, the polypi being removed, the underlying infective factor remained untouched, and unless this was dealt with the patient's condition might be aggravated.

Gastric Secretion and Digestion.

Dr. BRAY then made some remarks on the hypochlorhydria of asthma. He showed the result of 100 fractional test meals on asthmatic children, aged 6 months to 10 years, at Great Ormond Street. In 12 per cent. of the cases no specimen was found to contain any free hydrochloric acid, and in 45 per cent. never more than ten units. The secretion generally was below a low normal average for the age and for the type of test meal used. The possibility was that there were either mechanical defects of secretion, or the mucus, being slightly alkaline, combined with the acid and so neutralized it. Acid therapy had been used in the treatment of these cases, and although there had not been time for any clear indication of *results*, it appeared that the larger percentage of cases showed some improvement in the frequency or severity of their attacks, and there was a rapid return of appetite and gain of weight.

Dr. F. T. HARRINGTON (Newcastle) discussed the effect of digestion. He had many patients who had been freed from broncho-spasm and attained perfect health, in whom the treatment had been nothing more than the correction of bad habits in diet. One of the most common statements volunteered by the patient was that if he had not to eat he would not have broncho-spasm. The relationship between asthma and digestion was shown by the frequency with which vomiting would cut short an attack of asthma. The natural cure of a spasm was to empty the stomach of unsuitable or undigested food and to restore the function by insisting on digestible food, thorough mastication, proper intervals between meals, digestives, and other methods calculated to improve digestion. If the blood stream were charged with the irritating products of imperfectly digested food, one of the most frequent organs to be affected would be the nose. The mucous membrane became inflamed, oedematous, and highly sensitive, with the result that a coughing or sneezing reflex was readily

produced, and broncho-spasm frequently occurred. Ethmoiditis was not a cause of asthma; it had a trigger action only. With improved digestion the nasal mucous membrane, which had been red, irritable, and catarrhal, would often become pale and insensitive. If he had to pick out one article of food which appeared to do more harm than another in asthma it would be milk.

Dr. HURST said that it was a clear advance to have elucidated the hypochlorhydria of asthma as Dr. Bray had done, but he hoped he would not be content with giving his patients hydrochloric acid, but would get them to secrete their own acid. There seemed to be a difference in this respect between the child and the adult, acid deficiency being much more common in the former. Out of forty cases in adults twenty-four showed perfectly normal test meals, and four were above normal in acid content. There were three cases of complete achlorhydria, with no trace of acid, and as a result of treatment of the stomach, without giving them hydrochloric acid, they were now excreting their acid again. In some cases the removal of affected tonsils would restore the normal secretion of gastric juice.

Dr. E. P. POULTON suggested that in the taking of the first test meal some psychological factor might be at work in the case of children, and it would be well to repeat the test meal before the patient had any washing-out treatment. Dr. JOHN ADAM thought the hypochlorhydria in some adults examined was the result of defective ferment action of the stomach; bad diet was one of the contributing factors.

Serological Aspects, Blood Picture, Excretion.

Dr. JOHN FREEMAN (St. Mary's) dealt with the evidence afforded by Prausnitz's reaction for the passage of foodstuffs from the gut into the circulation. He described an experiment carried out on students at St. Mary's. The skin of the forearm of two students was injected with a serum from a fish-sensitive patient, and into the other forearm he put some of his own serum as a control. One student was given a dinner consisting of a considerable amount of fish; the other had no fish. The forearm of the first student became very red and swollen where the serum from the fish-sensitive patient had been injected, while the forearm of the other student did not react at all. Not that the latter escaped, for two days later he had a cod steak, and shortly afterwards developed a most marked reaction. It was not possible to escape the conclusion that the actual thing to which a man was sensitive got through into the blood stream and caused the local reaction. Prausnitz's reaction was a very good test for all kinds of asthmatic theories, especially some theories of the psychologists.

Dr. MARJORIE GILLESPIE (Asthma Research Clinic, Stobhill Hospital, Glasgow) gave an account of variations in *eosinophilia* seen in asthma. Of the cases which she had been studying for the last six months, only two had an eosinophil count of under 4 per cent., while the normal count was usually 2 per cent. The average count in these patients was somewhere between 7 and 10 per cent., but a good many were over 10 and a few over 20 per cent. The eosinophilia varied according to the state of the patient. During an attack, in the majority of cases, there was a fall to perhaps half the former percentage. There was a fall after giving adrenaline, but no effect after giving glucose. The amino-acids in the blood were raised when the eosinophil count was high, but the rise was not relative. Dr. BRAY said that in his cases the average eosinophil count was 7 per cent., with variations from 3 to 23 per cent. In normal children the figure was 2 per cent. with 10,000 leucocytes, whereas in these children it was at lowest 3 per cent. with 15,000 or 18,000 leucocytes.

Dr. F. A. KNOTT (Guy's Hospital) contributed some observations on the examination of the sputum and the faeces in asthmatics. The bacterial picture of the sputum was as follows:

	No.	Skin reaction.
Micrococci	10	0
Moulds	3	2+ 1-
Gram-negative	43	74% positive.

The faecal examination gave the following results in 120 cases:

	No.	Presence of lactose fermenters.
Excess undigested protein ...	37	17- 20-
Excess starch	17	10+ 7-
Starch and Protein	7	2+ 5-
Fatty excess	0	- -
Normal	59	6+ 53-

Urinary Proteose.

Dr. G. H. ORIEL (Guy's Hospital) spoke of the significance and therapeutic value of urinary proteose in asthma. An attempt had been made to prove whether the substance isolated was specific. During an attack of asthma what was called the proteose effect increased to about ten times what it was in the interval. The normal person turned out a small amount of proteose a day, and did not give positive skin reactions with it. Discussing the origin of this proteose he said that there were certain breakdown products in the gut which, if they got through, should be capable of sensitizing a patient. On a meat-free diet it was well known that eczematous and asthmatic patients tended to improve. If sufficient glucose were given, far less of this substance was excreted, and it did not as a rule give positive skin tests.

Dr. H. W. BARBER described some clinical results of Dr. Oriel's treatment with urinary proteose, but the cases in which he had employed injections of proteose had not been asthmatics, except that some of them had asthma in addition to the cutaneous symptoms for which primarily they were treated. Very dilute solutions were used—1 in 1,000,000 or thereabouts—and of these solutions only a small quantity was given—0.1 to 0.25 c.cm.—so that the reactions which were produced must, he thought, indicate specificity. He had tried this in rheumatoid arthritis associated with psoriasis and had got an acute reaction. It had been tried in urticaria, prurigo of various kinds, and certain types of eczema, as well as other conditions. In selecting cases he had made a choice of difficult ones of long standing, and had used great care to avoid any psychic factor. In cases of urticaria the method was strikingly successful; some eczemas did very well; uncomplicated psoriasis seemed to be little influenced, if at all, but when associated with rheumatoid arthritis the case did well under treatment, both as regards the rheumatoid condition and the psoriasis. He believed, after two years' observation, that the proteose in cases of sensitization did contain what might be looked upon as a specific antigenic substance.

Nasal Conditions.

Mr. C. GILL-CAREY (Guy's Hospital) dealt with sinusitis in asthma. In a group of cases of asthma which he had thoroughly examined for the presence of sinusitis, only some 50 per cent. had anything the matter with the nasal sinuses. There were two distinct types of sinusitis in these patients. A small proportion had a suppurative type of sinusitis, localized to perhaps one or two sinuses, and in this group rhinological treatment seemed to give better results than in the other group, which showed a generalized thickening of the lining membrane. This second group presented enormous difficulties in treatment. Amongst these people with hyperplasia were a certain number that got definite benefit from nasal treatment, though often the benefit was only temporary. Sometimes the return of the asthma might be due to inefficient surgery; at other times there appeared to be nothing wrong with the nose, and yet the asthma came back. He was inclined to think that the nasal condition was also the result of whatever was causing the asthma.

Dr. HARRINGTON described the technique of diastolization in nasal conditions associated with asthma. The aim of the treatment was to improve the nasal airway and reduce the sensitivity of the nasal mucous membrane. The apparatus consisted of thin rubber bougies shaped to the nasal fossa. The suitable type of case was one of nasal inefficiency not associated with pus or with bony deformity.

One result of the meeting was the formation of an Asthma Research Club, to meet informally in the various laboratories and clinics, with Dr. Freeman as honorary secretary.

British Medical Journal.

SATURDAY, JUNE 21ST, 1930.

CURRENT VIEWS ON THE ASTHMA PROBLEM.

IT was a happy inspiration of the Medical Advisory Committee of the Asthma Research Council to organize a scientific meeting at which both those who are working under the auspices of the Council and independent investigators should give an account of their labours. An opportunity was thus given for co-ordinating the results obtained by different lines of approach in different centres, and the interesting discussion which is reported on another page will doubtless stimulate the authors of the original communications to renewed efforts to solve the many problems connected with this most puzzling disorder.

Professor R. J. S. McDowall's introductory remarks on the physiological aspects of asthma gave a valuable survey of the whole subject, which is very necessary for those engaged in investigating isolated features to bear in mind. He accepted the definition of asthma which the chairman of the meeting, Dr. A. F. Hurst, had suggested several years ago—a constitutional condition, in which the nervous mechanism of the bronchi is in an irritable state, rendering it liable to periods of excessive activity as a result of chemical, reflex, and psychological stimuli. Dr. G. W. Bray found that one or other parent of no less than 70 per cent. of asthmatic children had suffered from asthma, hay fever, urticaria, or migraine, and that in one-third of these cases both parents had been affected. Dr. L. J. Witts pointed out how frequently asthma in children is associated with other allergic conditions. The recognition of the constitutional and inherited factor in asthma brings with it some hope of successful prophylaxis. Asthma in children can so often be cured by attention to the digestion and general hygiene, that it should be possible, by proper supervision of the children with asthmatic parents, to prevent its development. As a considerable proportion of all cases of asthma begin in childhood, this would prove the first step in the solution of the problem which the Asthma Research Council was founded to discover.

It has long been surmised that an alimentary toxaemia may be one of the most important factors in producing asthma, and Dr. James Adam has done much in the past to emphasize this aspect of the question. An insight into the nature of the digestive factor has now been afforded by the important investigations carried out, with the aid of grants from the Asthma Research Council, by Dr. Bray at the Great Ormond Street Hospital for Sick Children, and by Dr. G. H. Oriel and his colleagues at Guy's Hospital. Dr. Bray, in a series of 100 fractional test meals given to asthmatic children between the ages of 6 months and 10 years, found achlorhydria in 12 per cent. of the cases and hypochlorhydria in 45 per cent. Administration of hydrochloric acid generally leads to a diminution in the frequency and severity of the attacks, together with a return of appetite and gain in weight. Dr. Hurst has shown that achlorhydria and hypochlorhydria are more often secondary to gastritis than constitutional in origin, so that removal of such causes as septic foci in the mouth, throat, and nose, and lavage of the stomach with weak hydrogen peroxide, may be expected to restore the secretion to normal. In three cases of complete achlorhydria in a series of 40 adult asthmatics under his care, treatment of this kind had led to the return of a normal secretion of acid with considerable improvement of the asthma. Dr. F. A. Knott found undigested meat fibres in the stools of 44 out of 120 cases of asthma, whereas starch digestion was impaired in only 24 and fat digestion in none. This may well be the result of associated hypochlorhydria, and it explains the improvement in the condition of many asthmatics which follows restriction of meat. It shows, moreover, the need for thoroughly investigating each individual case, as in patients with excess of starch in their stools a reduction of meat is useless, but the avoidance of potatoes is followed by disappearance of intestinal flatulence, with consequent improvement in the asthma. Dr. Oriel has discovered that the majority of asthmatics excrete a proteose in their urine, the quantity of which is increased tenfold during an attack. The patient's skin reacts strongly to the intradermal injection of his own proteose, whereas normal people give no such reaction to the trace of proteose which is present in their urine. The urinary proteose is probably a product of protein digestion, and is absorbed from the bowel, as the quantity excreted is reduced on a meat-free diet. Desensitization by inoculating the patient with minute doses of his own urinary proteose has not only led to improvement in many severe cases of asthma, but Dr. H. W. Barber has found it strikingly successful in urticaria, in some forms of eczema, and in cases of psoriasis associated with rheumatoid arthritis.

The value of a full discussion between those working on different aspects of the asthma problem is well illustrated in the investigations at the Great Ormond Street and Guy's clinics; for Dr. Bray will now doubtless determine whether the hypochlorhydria of his patients is associated with albumosuria, and Dr. Oriel and Dr. Knott will determine to what extent the abnormalities they have discovered are dependent upon deficiencies in gastric secretion. If a curable gastritis is the primary factor in both groups of abnormalities, then its treatment may do away with the necessity for giving acid on the one hand and inoculation with albumose on the other. Dr. John Freeman described some striking experiments which prove that traces of proteins pass in an unchanged condition through the intestinal wall into the circulation, thus explaining the effect of certain foods in producing attacks of asthma and various cutaneous disorders. Dr. Knott has discovered that a Gram-negative bacillus with numerous eosinophil cells is frequently found in the washed mucous plugs expectorated by asthmatic patients. A positive skin reaction is given in 74 per cent. of such cases, whereas a reaction is never obtained with micrococci isolated from the sputum. This appears to be due to the fact that a histamine-like substance is produced by the Gram-negative bacilli, and it seems probable that the paroxysms in some cases of asthma may be due to the direct effect of this substance on the abnormally sensitive bronchi. These are the cases in which eosinophilia, which has been the subject of special study by Dr. Marjorie Gillespie, is generally highest. So much has been written on the nasal factor in asthma that the definite statistics given by Mr. Gill-Carey are very welcome. He finds that in 50 per cent. of cases sinusitis is present. These cases include the small group of aspirin-sensitive patients, to which Mr. F. Coke has drawn attention; polypi are always

present, and their removal results in actual aggravation of the symptoms unless the underlying ethmoiditis is adequately treated. When the whole nasal mucous membrane is in a sensitive state without any well-localized sinusitis, treatment by "diastolization," the technique of which was described by Dr. F. T. Harrington, is often of service.

The clinics founded by the Asthma Research Council have certainly justified themselves, and we can only hope that sufficient financial support will be forthcoming from the thousands of sufferers from asthma and allied disorders to make it possible for these clinics to continue the good work so auspiciously begun.

ECONOMIC PROBLEMS OF UNIVERSITIES.

As one half of the world does not know how the other half lives, some of the statements of fact in the report of the University Grants Committee for the academic year 1928–29[1] may cause surprise in many minds. Is it generally known, for instance, that of the total income—£5,174,510—of the universities and university colleges of Great Britain, 46 per cent. is obtained through grants by Parliament and by local authorities? The contribution from endowments is only 14 per cent., and from tuition fees 23 per cent. Again, it is possible that in some minds the notion still lingers that universities are mainly for the well-to-do. As a matter of fact, inquiry has shown that over 40 per cent. of the students are "assisted students"; and the committee is convinced that if comprehensive information were available, the number of assisted students would be found to be little short of 50 per cent. of the total number.

The University Grants Committee reports to the Treasury once a year; but towards the end of each quinquennial period it makes a tour of the universities and university colleges, and the report for the last year of the period contains a review of the progress made, and suggestions for the amount and objects of the Treasury grant for the ensuing five years. In the year 1923–24 the Treasury grant was £1,273,000. The annual grant was then raised to £1,550,000 per annum. On the recommendation of the committee Mr. Snowden has now made provision in the Estimates for an increase of £250,000 in this vote. Among the objects for which the committee feels that an increase in the vote is needed are improvement in the salaries of teaching staffs and the expansion of libraries. The man in the street will probably be surprised to learn that the average salary of a professor at a university is something less than £1,100 a year. An interesting question which is not answered in the statistical tables at the end of the report is, how many of the twelve professors with an income of £2,000 are medical men attached to hospital units? In any case the incomes of these twelve professors have raised the average, more than half of the 747 university professors having incomes below the £1,000 level. The state of assistant professors and readers is still worse. Their average income is £632. The section of the report dealing with this question of salaries is written with well-balanced judgement. The attractions of a university career are by no means minimized, but the committee is convinced that additional income for salaries is urgently required. It makes wise suggestions on the gradual attainment of improvement; and it urges concentration by the universities upon securing their academic foundations before attempting elaborations of the superstructure by pursuing a "forward policy" of expansion and development.

At the present time there are nearly 45,000 university students in Great Britain. Not counting the ex-service men who were being educated in 1923–24, this represents an increase of 3,000 over the number in the last quinquennium. The increase is entirely amongst the men; and though many causes for this may exist, it is regarded as being partly due to depression in commerce and industry. In bad times men go to the university—with a view to entering the more sheltered profession of teaching—rather than into business; and hard-hit families cannot afford to give a university education to daughters as well as to sons. It must not be forgotten, however, that the largest decrease in numbers is in medicine, a faculty in which the number of male students has fallen from 8,977 to 7,279 in the five years, and of females from 2,020 to 1,108. The number of male dental students has fallen from 1,018 to 630. In arts, on the other hand, there has been a remarkable change; and the percentage of students reading for an arts degree has risen from 34.7 to 44.6. The committee notes with some anxiety that there is a tendency to pay professors in the faculty of arts less than in science faculties. The report deals at length with the difficult problem of combining research work with teaching and administration, a problem for which no solution has hitherto been found, though in two universities, Cambridge and Edinburgh, the difficulty has been mitigated by relieving a professor of his teaching duties for part of a session in order that he might pursue his own line of investigation undisturbed. The committee hopes also that the universities will find it desirable to set limits to the external responsibilities they permit themselves to assume. All manner of bodies, from Government departments downwards, now thirst for "expert" advice, and seek the co-operation of the trained intellects of university staffs. Therein the committee scents danger, because the proper performance of the functions of advancing knowledge and teaching students leaves most universities with little margin for other purposes.

The report of the University Grants Committee is an admirable and judicious exposition of the difficulties with which universities have to contend; and if bureaucracy were content in all cases to exercise its control of public funds through similarly discreet and sympathetic bodies, it is possible that little fault could be found with that system of government.

MEDICAL ADMINISTRATION IN INDIA.

THOUGH, in the first part of its report[1] on the working of the system of government, the growth of education, and the development of representative institutions in British India, the Simon Commission deals very shortly with the medical services, it does not underestimate their importance. "The maintenance of the European elements in other services," states the report (p. 278), "is dependent upon the Government's ability to provide qualified European doctors for the treatment of officers and their families." And again, in dealing with the part that the Indian Medical Service has played, and must continue to play, in the medical administration of India, the Commission states: "We gladly recognize the enthusiasm of Indian public men for the improvement of medical facilities. But enthusiasm without adequate standards has its dangers; and the loss of contact with the standards and progress of Western medicine which would be entailed by

[1] Cmd. 3568. Report of the Indian Statutory Commission, vol. I. London: H.M. Stationery Office. 3s.

a failure of recruitment for the Indian Medical Service would, we are convinced, be disastrous for the future of the public health of India." Two reasons are given by the Commissioners for the difficulty that the Indian Medical Service has experienced in recent years in recruiting its full complement of officers. First, as a result of the Lee Commission's recommendations, the number of Indian Medical Service officers employed under provincial Governments is now limited to those required to supply a medical reserve for the Indian Army in war and to provide treatment for the European members of the services and their families—the medical staff of the provinces, over and above this, being provided by provincial medical services. Secondly, the new policy in relation to local self-government limits the effective powers of the civil surgeon for medical administration. One of the attractions of the Indian Medical Service has been that it has allowed a certain number of officers to transfer to service under the civil administration, their normal appointment then being that of civil surgeon of a district. These officers, working in close co-operation with the district officer, were formerly able to ensure that measures they thought necessary for the public health of the district would be carried out. Since, however, much of the medical administration has been placed in the charge of local self-governing bodies under non-official chairmen, civil surgeons have only been able to offer advice where once they issued orders. The civil surgeon still remains the medical representative of the provincial Government in relation to any matter over which it retains direct control; in particular, he is in charge of the headquarters district hospital. A failure of recruitment to the Indian Medical Service would have, in the opinion of the Commission, a very serious effect on the public health. Deaths in India from preventable disease each year amount to five or six millions. "The problems presented by such enormous figures can only be attacked by persistent research by highly trained and enthusiastic medical investigators, and a medical service recruited provincially in India will be no substitute in this regard for one with the exceptional standards and traditions of the Indian Medical Service." In a paragraph in Section VI, on the need for university reform, the Commission makes passing reference to the extensive unemployment of university graduates in India, and remarks that "the provision of specialized training for the professions of law, medicine, engineering, and for commerce, industry, and agriculture, exceeds in many cases the absorptive capacity." The second volume of the report, dealing with future developments, will set out the Commission's conclusions and recommendations. It is to be published on Tuesday, June 24th.

THE STORY OF THE "M.A.B."

THE Metropolitan Asylums Board has disappeared by reason of the transfer of its duties to the London County Council, but the disappearance of the Board is due to no shortcomings of its own, and indeed its supplanters unite to praise it. Its sixty-three years' work makes a notable chapter in the story of social amelioration and humane effort, and we are glad to have it put on record, even in so slight a form as to be little more than minutes, in *The Metropolitan Asylums Board and its Work, 1867–1930*,[1] which is a compilation by the late clerk of the Board, Sir Allan Powell. The initials "M.A.B." have been familiar to two generations of Londoners, but although the Board had to make provision for a daily population of 30,000, and controlled about 70 institutions, not counting such places as ambulance stations, few citizens of the metropolis could have passed an examination in its status and functions. The word "asylums" in its title gave rise from the very first to misunderstanding. Thus, in the first year of the Board's existence the Mile End guardians wrote that they were keeping a dangerous lunatic in their workhouse, and would be glad to know when the asylums to be erected by the Board were likely to be ready. The Board replied that it was proceeding with the proposed asylums for imbecile patients with all possible dispatch, but it had no power to provide for the class of lunatics to which reference was made. The reason for the Board's foundation in 1867 was that it might undertake for London as a whole branches of work which at that time were the duty of separate boards of guardians of the poor, but which could not be adequately carried out in one great city by a number of independent bodies with varying needs and resources. In tracing the Board's work in a number of useful directions, Sir Allan Powell remarks that at first, in respect of every disease, the admissions to the Board's institutions were limited to the pauper class, but in the natural order of things it was found necessary to throw open the doors and make the need for treatment the basis of admission rather than the lack of means. Mental cases formed an exception to this rule, and the pauper limitation remained, though some widening of the class of case treated took place here also. An interesting sketch is given of small-pox epidemics. The first with which the M.A.B. was called upon to deal was that of 1870–72, when 16,000 cases were admitted to the Board's hospital, in which 3,000 died. In the epidemic of 1901–2, 7,000 patients were admitted in three months, and 1,628 died. Since then the series of years of low incidence has remained unbroken, though a mild subtoxic type has lately been prevalent. Comment is made on the immunity of the Board's staff. At the outbreak of the epidemic of 1901–2, the number of small-pox cases dealt with since 1884 was 17,900, and among the staff of 2,198 persons there was not a single instance of the disease being contracted where there had been successful re-vaccination. Those who are familiar with the fine fleet of ambulances to-day will find it difficult to imagine the time, early in the Board's history, when cases of infectious disease were conveyed to hospital in hired vehicles, which stopped on the way at public-houses for the refreshment of the driver and the friends of the patient who accompanied him. Fifty years ago the Board was empowered itself to transport patients from home to hospital. The early ambulances were four-in-hand horse vehicles, and in these 1,600 small-pox cases were conveyed to Dartford. It is not so very long since a familiar sight in the streets was urchins running behind the Board's slow-moving horse ambulance shouting "Fever!" The mechanization of the service began in 1902, when a steam ambulance was introduced, with a capacity for eight stretchers, and a road speed of five miles, with a man in front carrying a red flag. The horse finally received honourable dismissal in 1912. Another fine story told in this volume is the work of the Board in housing war refugees. Altogether, one feels that the M.A.B. deserved a better fate than obliteration.

THE B.C.G. DISASTER AT LÜBECK.

DURING the past week there have been several more deaths among the infants treated at Lübeck by B.C.G. inoculation. In most of the fatal cases the interval between inoculation and death has been under two months, the more recent deaths having been among the infants treated in April. As inoculations were made until the end of April it is to be feared that further deaths will occur during the next three or four weeks. The representatives sent out from England by the Medical Research Council—Professor Georges Dreyer, chairman of the Council's committee upon the bacteriology of tuberculosis, and Captain S. R. Douglas, director of the Council's department of

pathology and bacteriology in the National Institute for Medical Research—were, we understand, given every facility for investigation both at Lübeck and in Berlin. We may hope that the information they gathered will serve to guide the Council in deciding on future lines of research in B.C.G. immunization. It is opportune to recall here that the committee set up by the Medical Research Council in 1927 to investigate B.C.G. decided to confine its attention to statistical and bacteriological studies, and in fact the Council has so far promoted no clinical trials of B.C.G. in this country. On its behalf, however, Professor Major Greenwood has examined the statistical evidence relating to the use of B.C.G. in France; Dr. A. Stanley Griffith, working in the whole-time service of the Council at the Field Laboratories, Cambridge, and Professor Dreyer, at Oxford, have investigated the bacteriological basis of the method; and Dr. Griffith and Professor J. B. Buxton have studied the protection of calves against tuberculosis, using their own modification of the Calmette method. Accounts of these investigations have appeared in the annual reports of the Council and in the reports of the Chief Medical Officer of the Ministry of Health.

A YEAR AT THE NATIONAL PHYSICAL LABORATORY.

THE report of the National Physical Laboratory for 1929[1] contains a detailed account of the many investigations on which that institution is continually engaged. These cover the fields of general physics, radiology, acoustics, optics, electrical standards and measurements, wireless, metrology, aerodynamics, and metallurgy. During last year the physics department of the Laboratory was engaged on the measurement of several grams of radium purchased by the National Radium Trust for distribution by the Radium Commission to the centres authorized to receive it. This work has involved the testing of the platinum containers for leakage as well as the determination of the radium content. An instrument has been designed at the Laboratory for the rapid visual identification, with the minimum of handling, of the large numbers of radium needles, tubes, and applicators which come to Teddington for testing. There was noted during the year a marked increase in the number of tests on feebly active preparations, such as radio-active waters, ores, luminous compounds, and the like. In *x*-ray measurement the workers in the department have been establishing the international unit of radiation, the "Roentgen," or "*r*" unit, which was adopted at the Stockholm Conference in 1928, and measuring the pa-tille dose in this unit. Investigation into certain problems relating to the energetics of *x* rays has been started, and the construction of a constant voltage generator for this purpose is well advanced. Among the problems which it is proposed to examine is the variation of *x*-ray output with tube voltage, anticathode material, and the angle which the *x* rays make with the target surface and with the exciting cathode rays. The testing of protective materials and the inspection of *x*-ray equipment and hospital installations in accordance with the recommendations for *x*-ray and radium protection have been continued. Some interesting work has also been done on sound, a line of research to which little attention was paid until recent years. The production, reception, and analysis of sound and speech, and their reproduction, transmission, and magnification for broadcasting, telephony, and similar purposes, have brought many problems to the Laboratory. Experiments are in progress for the Aeronautical Research Committee with the object of reducing the noise of the flight of aeroplanes. High speed in an aeroplane contributes much to noisiness; an increase of 100 feet per second in speed multiplies the sound tenfold. The noise in the cabin of an aeroplane is stated to be one thousand times that in an express train. A portable noise-measuring instrument has been devised for preliminary work, and a number of measurements of air-screw noises have been made. Street noises, in particular the noise due to motor horns, are also being investigated. On the subject of glare—a parallel infliction—the Laboratory is working on the effects of coloured light sources, and on the problem of vision under night-driving conditions. Another useful side of the National Physical Laboratory's work is temperature research undertaken for the Food Investigation Board, including a study of distant-reading thermometer outfits. An electric resistance thermometer designed at the Laboratory for cold storage work has been patented. A refrigerating railway truck, built for one of the railway companies, has been the subject of test. The truck is provided with a small methyl chloride refrigerating plant driven from the axle. A number of investigations have been made on long-distance journeys, which have shown that the plant is capable of cooling the truck and its cargo sufficiently rapidly, and also that the rate of temperature rise when the plant is not in operation is sufficiently slow. One part of the routine work of the Laboratory is the testing of clinical thermometers. More than ten thousand of these were tested last year, and the demand for individual certificates showing the actual corrections at various points of the scale has increased by 30 per cent., as compared with the number issued in the previous year. An inspection by the General Board of the Laboratory will take place at Teddington on June 27th from 3 to 6 p.m. Experiments and apparatus will be shown in the various departments, and the gardens of Bushy House will be open to visitors during the afternoon.

FOUNDATIONS OF MODERN SUPERSTITION.

"THE main interest of Egyptian medicine," writes Garrison, "lies in its proximity and relationship to Greek medicine." An interest of even greater concern to the comparative folklorist is brought out by Mr. Warren R. Dawson, who, in his book *Magician and Leech*,[1] shows how to Egyptian medicine may be traced many of the superstitions that are prevalent even at the present time. A remarkable example of the vitality of superstition is in the survival of the custom of making sick children in extremis swallow skinned mice. This procedure, which was extant in this country within living memory, is actually recommended in a papyrus written about 1400 B.C.; but it must have been prevalent since the dawn of Egyptian History, for remains of mice have been discovered in the alimentary canals of the bodies of children found in a pre-dynastic cemetery in Upper Egypt; moreover, there is evidence that these mice had been skinned. In the presence of such a custom, supported by the empirical practice of sixty centuries, most medical procedures of to-day look uncommonly like upstarts. In the Ebers Papyrus the blood of bats was recommended for use as a depilatory, but at some time or another the Egyptian word for bat was misread as bug, with the result that the blood of bugs found a place in the mediaeval pharmacy, and remained there for several centuries. This is perhaps one of the earliest examples of error arising from the careless reading of prescriptions, though in this case the consequences do not appear to have been serious. In view of the belief prevalent in some quarters even to-day that the blood of menstruating women exercises a toxic action on plants, it is interesting to note that phyto-pharmacology was applied by the ancient Egyptians as a test for pregnancy. A woman subjected to this test watered spelt and wheat with her urine; if the wheat grew the foetus was a male, if the spelt grew it was a female, and if neither grew the woman was not pregnant. Culpeper gives a modified version of

[1] *Magician and Leech*. By Warren R. Dawson, F.R.S.E. London: Methuen and Co., Ltd. 1929. 7s. 6d. net.

this test, which thus lingered on for about 3,000 years. It would seem, therefore, that the survival of a test is by no means jeopardized by the fact that its validity can easily be disproved. Indeed, the uncritical imagination is so much more likely to be arrested by the irrational and bizarre than by cold reality that the social survival value of an idea might seem to be in a direct ratio with its absurdity. In defence of empirical practices against scientific criticism it is a favourite rationalization to invoke a hypothetical wisdom of the ages as embodied in a continuous tradition. Mr. Warren Dawson gives in his book many interesting examples of the kind of wisdom such traditions may sometimes preserve.

THE PHYSIOLOGICAL SOCIETY.

THE next meeting of the Physiological Society will be held to-day (Saturday, June 21st), at 2.30 p.m., in the Department of Physiology, University College, London, with Sir Charles Sherrington in the chair. The subject for consideration is "chronaxie"—the latent period between the application of an electric stimulus to a muscle and its contraction. A discussion on "Chronaxie and central nervous activity" has been arranged under three headings, each of which will be introduced separately by Professor Louis Lapicque. Dr. Henri Laugier and Dr. Catherine Veil of the Sorbonne, and Professor Henri Fredericq of Liège, have promised to contribute to this discussion. During the tea interval Dr. Georges Bourguignon will demonstrate the technique of chronaxie measurements on human subjects, and Dr. Léon Brillouin will demonstrate and explain his new apparatus. We are asked to state that the society will be pleased to receive interested medical men as guests. In the evening a dinner in honour of Sir Edward Sharpey-Schafer will be held at the Trocadero Restaurant, under the chairmanship of Sir Charles Sherrington. There will be a meeting of the society in the Department of Physiology, University of Oxford, on Saturday, July 5th, and a discussion on "Colloid science applied to biology" will be held at Cambridge from September 29th to October 1st.

THE new Bethlem Royal Hospital at Monks Orchard, Eden Park, Beckenham, will be opened by Her Majesty the Queen on Wednesday, July 9th, at 3 o'clock. It stands on a site occupying 330 acres. The foundation stone was laid by H.R.H. Prince Arthur of Connaught on July 10th, 1928.

LONDON HOUSE.

A STUDENTS' HALL OF RESIDENCE.

THE establishment of a university hall of residence in London for men students from the provinces, but particularly from overseas, is being actively pursued. An excellent site has been secured in Bloomsbury, where a hall, to be called London House, will be erected. While closely associated with the University of London, the hall will be an independent institution with a governing body including representatives of London University, the Royal Colleges of Physicians and of Surgeons, the various institutions of engineers, and other societies. A small private company, known as the Dominion Students' Hall Trust, has been formed to further this object, and a fund of £250,000 is being raised for the purchase of the site and the building and equipment of this new centre of student life. Towards this sum £130,000 has been subscribed by City interests, including donations of £5,000 each by the Corporation of London and the Rhodes Trustees.

The first governors include Mr. L. S. Amery, formerly Secretary of State for the Dominions, Lord Atkin, chairman of the Council of Legal Education, Sir W. H. Beveridge, director of the London School of Economics, Mr. H. A. L. Fisher, Warden of New College, Oxford, and formerly President of the Board of Education, Lord Melchett, Lord Lothian, and Mr. F. C. Goodenough, chairman of Barclays Bank, who is honorary treasurer of the fund. While the student from the provinces will be admitted, the hall will be primarily for the British student from the Dominions and Colonies, for whom there is a growing need to provide the right accommodation, since every year sees an increase in the numbers of such men coming to London both for undergraduate and for post-graduate work in every faculty.

Mansion House Meeting.

Recently an influential meeting was held at the Mansion House, presided over by the Lord Mayor, in support of the movement, when a letter was read from the Prime Minister giving an assurance of the Government's sense of the importance of the venture in relation to the establishment of the proposed post-graduate hospital and medical school at Hammersmith, towards the creation of which the Government has made a grant of £250,000. The Lord Mayor said that the need for such a hall of residence had been felt for years. As Dominion students came in increasing numbers to London, the duty to provide that corporate life wherein the students might mingle with British students from the home country became imperative. Mr. L. S. Amery remarked that the genius of Cecil Rhodes had divined what collegiate life could give to the younger generations from overseas, and this had been confirmed by the experience of the last twenty-five years at Oxford. But Oxford, said Mr. Amery, was not the only university to which Dominion students resorted. A large number came to London University, with its wide range of studies, its great hospitals, and technical schools, and these students had in the past been compelled to seek accommodation in boarding houses scattered throughout the metropolis. Mr. H. A. L. Fisher, in bringing to the scheme the blessing of the older university, said that the educational advantages of London were incomparable, and there was no department of knowledge in which London did not offer unrivalled opportunities. Other speeches in support were delivered by Mr. Stanley Bruce, late Prime Minister of Australia, the Hon. Sir James Parr, late High Commissioner for New Zealand, Sir William Clark, British High Commissioner in Canada, and Sir Drummond Chaplin, representing South Africa.

Lord Moynihan's Speech.

Lord Moynihan of Leeds, P.R.C.S., spoke for the medical profession. He referred to the lack of opportunity for post-graduate instruction in this country. This want was now being remedied by the setting up of the Hammersmith Hospital as a post-graduate centre. But neither hospital nor school was complete unless there was a hostel in connexion with them in order that students from overseas might be properly housed. "Above all things, it is the clash of one mind against another, the impact of one temperament against another, which does more good than all the other things, in my judgement, in a university education, and it is that which a hall of residence produces." Lord Moynihan described the recent arrangement whereby, for the primary Fellowship examination of the Royal College of Surgeons, examiners were being sent out to the Dominions—next year the examiners would go both to Canada and to Australia, but for the final examination the men must come to this country. "We have every possible advantage in London that the medical student or post-graduate from abroad can desire. We have the best material in the world. We have really, though the men themselves hardly believe it, the best men for teaching and for practice in the world. All that we want is the determination that we are going to have a residential hall where we can house those men as we open our arms wide to receive them."

We learn that on the freehold site in Bloomsbury which has just been purchased, it is proposed to build by stages a great hall and common rooms, and eventually to have a collegiate hostel of which it is hoped London and the Empire may be proud.

ALPHONSE LAVERAN AND HIS WORK.*

BY

JAMES H. SEQUEIRA, M.D., F.R.C.P., F.R.C.S.

CHARLES LOUIS ALPHONSE LAVERAN was born in Paris on June 18th, 1845, a year later than Patrick Manson and in the same year as Elie Metchnikoff and Wilhelm Conrad Rontgen. There is no doubt that heredity and family surroundings exercised a decisive influence on his mental and moral development. The Laverans were of Flemish origin, and Alphonse was the son and grandson of doctors. His father, Dr. Louis Théodore Laveran, was a renowned teacher at Val-de-Grâce, being professor of military medicine and epidemiology at the Army Medical School, an institution of which he was later director. He died in 1879, on the eve of the discovery which made his son famous. As a great teacher he cultivated in his son a love of Nature and a taste for exact observation. Laveran's mother, who belonged to an old Lorraine family, was born in a village near Metz. Her father was Commandant d'Artillerie Guénard de la Tour, and two of her maternal uncles were celebrated soldiers under Napoleon.

Alphonse Laveran passed his early days in Paris; later, as his father's military service determined, he moved to Metz and then to Algeria. In 1856 he returned to Paris, and, after a period at the College Sainte-Barbe, entered the Lycée Louis-le-Grand, where he finished his classical studies. As soon as he had obtained his baccalaureate he decided to follow his father's career, and commenced his studies at the School of Military Hygiene in 1863. This was followed by a four years' course at Strasbourg, which, at this time, excelled in the teaching of histology. In 1866 Laveran became an intern at the Civil Hospital, and obtained his doctor's degree for a thesis on the regeneration of nerves. After a course at Val-de-Grâce he was appointed aide-major to the Military Hospital St. Martin. At the opening of the Franco-Prussian war Laveran served with the ambulances at the battles of Gravelotte and Saint-Privât, and retired with the broken French armies into Metz, where he remained throughout the siege. It is almost impossible to realize now the appalling conditions. The be-sieged town was filled with casualties, most of the wounds were complicated with septicaemia, erysipelas, and gangrene, dysentery and typhoid prevailed; and the resources of the medical service were inadequate. On its capitulation Laveran was taken prisoner, but, being a doctor, he was speedily released: on returning to France he was appointed to the Military Hospital at Lille. Here he remained till the end of the war. In the civil war that followed he was at his old post at the Hospital St. Martin, where patients and staff were injured during the bombardment. These events culminated in the great conflagration of May, 1871, which destroyed the Tuileries, the Hôtel de Ville, and many other notable buildings.

In 1874 Laveran was elected to the chair held by his illustrious father at Val-de-Grâce, and his lectures and practical classes on pathology increased his reputation. A year later he published a treatise on the subject of his lectures. During this time he was assiduously attending the laboratory of Professor Ranvier to perfect his knowledge of histological technique. When his term of office at Val-de-Grâce expired in 1878 he was appointed to the province of Constantine in Algeria. Now began his studies of the blood and viscera of malarial patients. He soon came to the opinion that the pigmented elements, first figured by Virchow in 1848, which had hitherto been thought to be melanin-bearing leucocytes, were of a parasitic nature, but he was unable to complete his investigations, being transferred to Biskra. As there was very little malaria in Biskra, Laveran made a study of the variety of oriental sore known as Biskra button. Next year, in collaboration with Dr. Tessier of Lyons, he published a book on clinical medicine and pathology in two volumes, a work that reached its fourth edition in 1894. In 1880 Laveran was again appointed to the military hospital at Constantine, and resumed his studies of malaria.

The first notice of his historic discovery is found in the *Bulletin de l'Académie de Médecine de Paris* (1880, 2 sér., tome ix, p. 1235).[1] It is a simple record that M. Laveran addressed a note on a new parasite found in the blood of several patients suffering from malarial fever. There is no text. In the same *Bulletin* (p. 1346) there is a second note relating to a new parasite found in the blood of patients suffering from malaria. Here again there is nothing in the text except a few remarks by M. Colin. Laveran's first paper was a communication from Constantine dated December 15th, 1880, to the Société Médicale des Hôpitaux de Paris and published in the *Bulletin* of that society (1881, 2 sér., xvii, pp. 153-164). The author states:

"On the 20th October last, while examining by microscope the blood of a patient suffering from malarial fever I observed in the midst of the red blood corpuscles the presence of elements which appeared to me to be of parasitic origin. Since then I have examined 44 cases, and in 28 have found the same elements. I have searched in vain for these elements in the blood of patients suffering from diseases other than malaria. I have described the elements as Bodies No. 1, No. 2, and No. 3. Bodies No. 1 are elongated elements more or less tapering at the extremities, often curved into crescents, sometimes of oval form. They measure 8-9 thousandths of a millimetre. They are colourless, except towards the central part, where there exists a blackish spot formed of a series of rounded granulations, which appear to be pigment granules. Some of the bodies show on the concave side a pale curved line which appears to tie together the extremities of the crescent. Bodies No. 2 show different aspects in rest and in motion. At rest they are spherical and show a circle of granules of pigment. In movement there is a rapid change; very transparent filaments animated by active movement are seen outside the bodies. The filaments are symmetrical. A free filament of one of these bodies is figured. Bodies No. 3 are generally spherical but larger than No. 2, and show alterations in shape."

Although we have improved our microscopes and methods of staining we can recognize at once the completeness of this succinct description and the identity of his reproductions.[2] He discusses several possible objections in regard to the nature of these protozoa. Bodies Nos. 2 and 3, he observes, appear to him to be different phases of the same parasite. He remarks that the parasitic elements under consideration had hitherto been confused with melanin-bearing leucocytes, and he concludes that the presence of these parasites in the blood is probably the principal cause of the symptoms of malaria. This was confirmed in 1882, when he found the parasite in the same forms while studying malaria in the Roman Campagna. But to his questions, What becomes of the elements? How are they introduced? How do they cause the disease? there was, as yet, no answer. It was natural that Laveran's early observations on the haematozoon of malaria should be received with scepticism. Bacteria had been known since 1683, when they were observed and figured by Leeuwenhoek, whose only instrument was a small simple lens.[3] The improvements in microscopy, especially the development of the compound microscope, had increased enormously the number of micro-organisms known to science, but the haematozoon of malaria was the first pathogenic microbe of animal origin to be described. The work of the Italians was particularly valuable, Golgi made a notable contribution in his discovery of the plurality of the parasites of malaria.

In 1889 Laveran received the Bréant prize from the Academy of Science, and two years later, as professor of military hygiene at Val-de-Grâce, he published his *Paludism and its Haematozoon*, which was enthusiastically received. It was recognized, as Professor Ranvier said, "that the discovery of the haematozoon was not a matter of chance. It was the result of the perseverance and great talent of the observer." Many honours were

* Abstract of presidential address at the Laveran Jubilee Meeting of the Kenya Branch of the British Medical Association, which was devoted this year to the study of various aspects of malaria. A report of the proceedings appeared in the *Supplement* of March 22nd (p. 52).

[1] In the small room where the discovery was made plaques commemorating the event have been set up by the military doctors at Constantine and the civil practitioners in Algeria.

[2] Dr. Sequeira showed a lantern slide of a tracing of the woodcut in Laveran's original paper.

[3] Leeuwenhoek's papers were published by the Royal Society.

conferred upon him, not only by his own country, but by many foreign academies and learned societies, among them the Jenner medal of the Epidemiological Society. In 1894, having completed his term at Val-de-Grâce, a "narrow and paltry militarism" detailed him for administrative work at Lille and Nantes. (His character and independence had offended certain Ministers.) In these posts he had no hospital and no laboratory for his researches. When the expedition to Madagascar was being organized in 1895 his assistance was not invited, although the danger of malarial infection was generally realized. The atmosphere was uncongenial, but he carried out his duties with characteristic energy until the following year, when, in spite of the urgent protests of friends and colleagues, he retired from the service. Just over 50 years of age, and freed from official restrictions, Laveran offered himself as a voluntary worker at the Pasteur Institute, where he was welcomed by MM. Duclaux and Roux. He was appointed chief of the honorary service, and shared a workroom for several years with M. Mesnil. Here he extended his researches to the pathogenic protozoa of the animal kingdom, and described and studied a number of new organisms. These included the intracorpuscular haematozoa of birds, which are of special interest in relation to the work of Ronald Ross.

Although absorbed in his new work Laveran did not lose his interest in malaria. The fruitless search for the haematozoon in air, water, and soil led him to the conclusion that the organism must pass a phase of its existence in an animal host, and, like Manson, he thought that the host was probably the mosquito, which was well known in all malarious districts. Manson had already, in 1878, demonstrated the role of the mosquito in the pathogenesis of filariasis. Up to 1894 the predominant opinion was that flagellation was the result of the death and disintegration of the parasite. Manson, on the other hand, maintained that "since the flagella appear only when the malarial blood gets outside the body, their purpose must be to continue the life of the parasite in the outer world . . . for the purpose of infecting mosquitos which suck the blood of patients." MacCallum showed that the flagella were microgametes, and he and Opie proved the crescents to be sexual forms. At Secunderabad in 1897, Ronald Ross, then a major in the Indian Army, found in the stomach of two "spotted winged" mosquitos, bred on larvae and fed on a patient whose blood contained malaria crescents, certain pigment cells indistinguishable from those observed in malaria parasites. He confirmed these observations in another species of anopheles also bred from larvae, and sent in his report. A week later he was sent on official duty to Rajputana, and his researches were stopped for six months. Speaking many years later at the opening of the Ronald Ross Gate Commemoration in Calcutta (1927) Sir Ronald referred to Laveran as "his master" and to Sir Patrick Manson as "my sponsor and the man who put me on the right track." Fortunately Manson was medical adviser at the Colonial Office, and by his intervention Ross was transferred to Calcutta for "special duty." There he studied the details of mosquito transmission in the allied parasite of birds, as few malaria patients were available. Even when he had worked out the cycles of avian malaria his shortsighted superiors failed to realize the importance of his discovery, and he was sent to Assam to investigate kala-azar. It thus fell to the Italians—Grassi, Bignami, and Bastianelli—to verify Ross's observations in human malaria. The final and complete proof that malaria is carried from individual to individual by mosquitos, and by mosquitos alone, was made in 1900. At Manson's suggestion the Colonial Office and the recently founded School of Tropical Medicine sent Drs. Sambon and Low to live in a mosquito-proof hut for the three most dangerous months at Ostia, a heavily infected area in the Roman Campagna. They lived normal lives during the day, taking no quinine or any other precautions. The only condition carefully observed was that from sunset to sunrise they remained in their anopheles-protected hut; as a result they enjoyed complete immunity, while all their Italian neighbours were attacked by the disease. The complementary test was made at the same time. Mosquitos that had been fed in Rome on malarious patients were sent to London and allowed to infect the late Dr. Thorburn Manson[4] and Mr. George Warren, neither of whom had been abroad or exposed to malaria. Both developed the characteristic fever, and the haematozoon was found in their blood in the initial attack and in the relapses.

Laveran was naturally one of the strongest supporters of the malaria-mosquito theory, and soon developed its practical application. After an exhaustive study of the mosquitos of Corsica he presented a report in 1901 to the Academy of Medicine, urging that an organization should be formed to combat malaria on the lines suggested by the recent discoveries. The following year the Corsican Anti-malaria League (Ligue Corse contre le Paludisme) was inaugurated with Alphonse Laveran as honorary president. Under the energetic direction of Dr. Battesti the league devoted its attention to such matters as the destruction of breeding places, the prophylactic use of quinine, and propaganda in schools. A similar league was formed in Algeria during the next year, and organizations working on these lines are now found all over the world. It was the immediate development in this branch of research that cleared Havana of yellow fever and freed the Panama Canal zone of mosquito-borne diseases.

Among the many subjects which Laveran studied at the Pasteur Institute were the trypanosomes, and he and M. Mesnil described at least thirty new species. His book, *Trypanosomes and Trypanosomiasis*, published in 1904, became a classic. In the same year he reported the first case of infantile kala-azar, a disease now known to be widespread on the European and African coasts of the Mediterranean. In 1907 he received the Nobel Prize.[5] At this period the council of the Pasteur Institute decided to purchase an adjoining property, comprising a dwelling-house in the Rue Falguière and large stables and coach-houses. The house was made into laboratories, and the second story was placed at Laveran's disposal. The other premises were converted into stables, kennels, aviaries, and aquaria. To this laboratory of tropical diseases Laveran contributed 100,000 francs (then worth about £4,000) from his Nobel Prize. Here he worked from 1907 to 1922, taking his share of the courses on microbiology, malaria, piroplasmosis, leishmaniasis, and sleeping sickness. In his second floor apartment, the door of which was indicated by a modest visiting-card fastened with a tack, his advice and counsel were sought by workers from all parts of the world. In 1908 Laveran founded the Society of Exotic Pathology and was president for twelve years. The bulletins of the society bear witness to his amazing industry. During the war he served on numerous commissions and visited nearly every army corps. In the Salonika campaign his advice was, of course, of great value.

These duties must have imposed a heavy strain on a man of 70, but he continued to work at the Pasteur Institute, where only a single attendant had been left. Despite difficulty he brought out his book on leishmaniasis, which was similar in scope to his classic publications on malaria and trypanosomiasis. He presided at the centenary fête of the Academy of Medicine in 1920, but his strength was failing, and he died on May 18th in the same year as the British Father of Tropical Medicine, Sir Patrick Manson.

It would be difficult to give a finer example of sustained action or of higher ideals of duty. Laveran was devoted to his home and family. A man of rather slow speech he had inherited a certain reserve, but his kindness was always apparent to those who worked with him. The world-wide recognition of his contributions to medical science is shown by the honours he received at home and abroad. He was an honorary fellow of the Royal Society and of the Royal Society of Edinburgh, honorary fellow of the Royal Society of Medicine, of the Pathological

[4] Dr. Thorburn Manson's lamented death was not due to malaria.
[5] Ross had received it in 1902.

Society of Great Britain and Ireland, of the Society of Tropical Medicine and Hygiene, and of the Institute of Public Health. The University of Liverpool, which has done much to foster research in tropical disease, conferred upon him an honorary doctorate.

New Zealand.

[FROM OUR CORRESPONDENT.]

Social Insurance.

THE national scheme of medical service propounded by the British Medical Association has received some prominence in the cablegrams to New Zealand. Legislation in New Zealand may be considered advanced in many ways, but in this country there is no system of national health insurance apart from that which is connected with the various lodges or friendly societies. The public hospitals here are to a great extent under the control of the Government and of local bodies, and have unusually large out-patient departments, which lessen the need for a national medical service. Domiciliary visits are authorized to a very limited extent by the hospital and charitable aid boards, this being our nearest approach to a Poor Law medical service. The New Zealand Branch of the British Medical Association is not in sympathy with general medical insurance. Dr. Erwin Liek in his book *The Doctor's Mission* condemns at least the German system of medical insurance; he considers that the production of hypochondria, and the wholesale malingering to obtain incapacity payments, as well as other evils, outweigh its obvious advantages. The comments on the outlines of the scheme propounded by the Association may be invalid because of insufficient knowledge here of the actual proposals, but one of our leading journals, *The Dominion*, may be quoted to express the views of an influential class in New Zealand.

"Tendencies should be carefully studied in New Zealand before any attempt is made to introduce social insurance in its various forms. It is not only that great bureaucracies grow up and fatten on such schemes, but that the so-called beneficiaries are morally debauched, losing in self-respect, self-reliance, and independence. They are not even happy because they have put away the salt of life—its constant quest and effort and adventure and every spice of risk—to rest snug in a slack and savourless security. In fact, however discouraging it may be to reformers and however sad a reflection it may cast on weak human nature, experience suggests that social insurance tends to create the very ills it sets out to cure."

Hospital Policy.

The average daily number of occupied beds in the public hospitals of New Zealand in the eighteen years from 1911 to 1929 increased from 3.1 to 5.8 per 1,000. During the same period the number of in-patients annually receiving treatment rose relatively to the population to the extent of 148 per cent.; out-patient services developed to a still greater extent—that is, from 18,867 out-patients in 1911 to 73,952 in 1929. The gross annual maintenance cost of public hospitals has in the same period increased from £200,631 to no less a sum than £1,206,190 for last year, disregarding indirect expenses and also expenditure on district medical nursing and ambulance services. The Minister of Health states that the provision of public hospitals, including administrative expenses and interest, and depreciation charges, entails a burden on local and general taxation exceeding £1,000,000 per annum. If these figures continue to increase at the same rate it will not be long until hospital expenditure will become a very serious burden for the taxpayer. Under the present hospital system the class of people who pay most in taxation for the upkeep of public hospitals do not themselves obtain treatment in the public hospitals except to a very limited extent. Arising partly out of these considerations a conference was held recently of representatives of the hospital boards, the Health Department, the New Zealand Branch of the British Medical Association, and the New Zealand Section of the College of Surgeons of Australasia, and the following resolutions were adopted:

1. That all members of the community requiring treatment in hospital be eligible for admission to public hospitals.
2. That patients in public hospitals who need, because of the nature of their illness, accommodation other than in the large wards shall be provided for by an adequate number of one to four-bedded wards.
3. That patients voluntarily availing themselves of such special accommodation shall pay the full cost of maintenance, including overhead expenses, provided that no distinction is made in the case of patients unable to pay.
4. That the medical attendance of patients be in the hands of a visiting staff with the assistance of a requisite number of resident medical officers, the foregoing not in any way to interfere with the administration of the hospital or such powers as are already vested in the medical superintendent and stipendiary staff.
5. That each hospital board must determine the number of the visiting staff, but it be recommended that in arriving at a decision the board shall, consistent with the convenience and smooth running of the institution, appoint as many of the medical practitioners residing in the district as possible.
6. Subject to the approval of the board, that the right of attending their own patients admitted under Resolution 3 be extended to all practitioners except such as may for special reasons be deemed unsuitable.
7. That in making appointments to the visiting staff, and in determining the suitability or otherwise of practitioners for the privilege of attendance on patients, the hospital board should be guided by the advice of a special consultative body, or, in the case of the smaller hospital districts, by the advice of the Director-General of Health.
8. That such special consultative body comprise the consulting staff, if any, of the hospital or the senior members of the medical profession of the district, such senior members to be selected by the hospital board.
9. Patients unable to pay the ordinary hospital fees shall be attended by the visiting medical staff in an honorary capacity.
10. Patients entering the hospital and able to pay for medical attendance in addition to maintenance fees shall make their own terms with their medical attendant, who will be responsible for collection of his own fees.

Belgium.

[FROM OUR CORRESPONDENT.]

Progress of the Campaign Against Syphilis.

AN important statement has been published by Professor Bayet and Dr. Timbal detailing the results obtained during recent years in the reduction of nine-tenths of the prevalence of syphilis in Belgium. The number of chancres treated by the dispensaries and clinics fell from 2,504 in 1920 to 204 in 1927, and the incidence per 1,000 of primary syphilis in men on military service from 13 in 1920 to 0.43 in 1925; this incidence rose slightly to 0.59 in 1927, but it then fell again, reaching an approximate figure of 0.4 in 1928. All the available evidence, notably that obtained by recent investigations of the National League of Belgium against Venereal Diseases and of the health administration, indicates that, during the last two years the position has remained favourable. Yet here and there a slight increase is still manifest from time to time in the number of fresh infections; it may be that these sporadic outbursts are inevitable, and imply that the decline in prevalence has reached a stage below which it will be difficult to pass. Alternatively, the arrest of the fall in the statistical curves may be associated with the restrictive measures which came into existence in January, 1925. It would be premature to draw final conclusions yet, but, whatever may be the cause of this halt, the Government is determined to continue the campaign energetically. Its sanitary health visitors will follow up syphilitic women detected in the obstetrical departments of hospitals and ante-natal clinics, and will endeavour to secure the return of defaulters to

treatment centres. Such measures have obviously a considerable social bearing. Nevertheless, the Government believes that still more is necessary, and that the special measures enacted in 1926 and 1927 must be re-enforced on the following lines. Recognized medical practitioners will now, as before, be empowered to prescribe at the expense of the State such specific treatment as is necessary to ensure the curing of infective lesions; hospital consultations are to be re-established; post-graduate courses in syphiligraphy will be organized in the universities for final year students, and only those practitioners who possess certificates issued at the end of such courses will be permitted to benefit by the free supply of specific remedies.

An International Pharmacopoeia.

The Belgian Government has approached the Council of the League of Nations with reference to the second International Conference for the Unification of the Descriptions of Drugs, which was held at Brussels in September, 1925. It was proposed to establish an international organization to bring about unification of the national pharmacopoeias, and to set up certain special commissions. The Belgian Government has informed the general secretary of the League of Nations that the international agreement elaborated at the conference has now been ratified by a sufficient number of countries, and the view of the League of Nations is sought with regard to the creation of the contemplated international organizations.

Prophylaxis Against Tuberculosis in the Congo.

Legislative steps have been taken in order to deal with the increase of tuberculosis in the Belgian Congo. It has now been enacted that no one of foreign derivation may enter the Belgian Congo to live there unless he possesses a duly legalized medical certificate, signed by a registered practitioner in the country in which he is living, or in the country where he last lived, and certifying that he has no sign of open tuberculosis. Any person not of Congo descent who is living in that country and is found to be infected with open tuberculosis will be required to leave the territory within six months after the diagnosis has been established.

The Proposed Flemish Academy.

A very important debate was held at the Academy of Medicine on the proposal to create a Flemish academy of medicine, science, and fine arts. Professor Bordet made a strong speech on the danger innate in such a proposition. It was evident, he said, that the adoption of a measure of this kind would bring about a serious cleavage between men imbued by a like culture and ideal; they desired, on the contrary, to co-ordinate their work, maintaining the closest mutual relations in order to serve that still higher interest which was common to humanity—namely, the scientific interest. Belgian men of science refused to believe that they would be asked to accept this great dissociation, which would drive them to forget all that united them and concentrate on what might divide them. The academies were justly proud of having been, and of being, in the intellectual sense, the representatives of the whole of Belgium, one and indivisible. It was evident that the language question was of the first importance in matters relating to purely literary interests, but, in the case of science the position was wholly different. For the scientist languages were the means of propagating discoveries; he had no wish to confuse himself with the separating of mankind into different nationalities. Most scientists in the course of their work had to make use of foreign languages, such as English or German, and liberty in this respect was an absolute necessity for science. It was absurd to decree the use on all occasions of one particular language for discussions or scientific writings. To impose such a blind restriction based on linguistic rivalries and national aversions was an offence to science itself; it amounted to a complete misconception of what constituted the real dignity of science. The self-sacrificing devotion of scientists was based on the human and international nature of science, the part it played in drawing together civilized peoples, its task of linking men together in sincere co-operation to make life more peaceful and more pleasant, and thus to quiet those racial antagonisms which had caused so much evil and were still so often to be discerned. The text of Professor Bordet's speech, and the account of the discussion which followed, have been forwarded to the Government by the unanimous desire of the Academy, special attention being called to some of the considerations which were put forward in the course of the meeting.

Scotland.

The Prince of Wales's Visit to Edinburgh Royal Infirmary.

On June 12th the Prince of Wales paid a visit to the Royal Infirmary, Edinburgh, with the object of commending to the public the appeal made by the managers in connexion with the bicentenary of the institution. The Prince proceeded first to the George and Agnes Murray Home at Gilmerton. This institution, completed in the spring of the present year at a cost of £22,000, has been established as a convalescent home in connexion with the Royal Infirmary of Edinburgh, and is especially intended for invalid British soldiers and sailors. Lord Provost Whitson mentioned that the home would accommodate twenty convalescents. It had been provided out of funds left by the late Miss Helen Murray, and was designed to give the maximum amount of sunlight to all rooms at the time of day when they were in use. In declaring the home open the Prince remarked that he was proud to be associated at any time with an institution that could benefit ex-service men; he shook hands with the fifteen convalescent soldiers who are already in residence. Proceeding to the Royal Infirmary, the Prince was received there by the superintendent, Dr. G. St. Clair Thom, Mr. Henry Maw, secretary and treasurer, Miss Bladon, superintendent of nurses, and a number of the managers and honorary staff. After visiting a male surgical ward and a female medical ward, his Royal Highness planted a tree on the lawn between Wards 31 and 34 at the south side of the Infirmary to commemorate his visit. A tour of inspection was then made of the radiological department, where His Royal Highness showed special interest in an *x*-ray film illustrating the case of a man who had swallowed a safety razor which lodged in his stomach. He was also interested in the arrangements made for the radium received from the Radium Commission, which is stored in a special lead safe weighing three tons. Before leaving the institution the Prince visited the residency, where he signed his name on the dining-table that bears the names of all the residents who have passed through the institution since 1879, as well as those of distinguished visitors, including the King and Queen. He was presented by Dr. A. Logan Turner with a copy of his book dealing with the history of the Royal Infirmary of Edinburgh. After a visit to the National War Memorial in Edinburgh Castle the Prince was entertained to lunch in the City Chambers. Here the Lord Provost proposed his health as Duke of Rothesay, Steward of Scotland. The Lord Provost remarked that the visit had been made on account of the celebration of the bicentenary of the Royal Infirmary, which had begun in a small house with six beds at Robertson's Close in 1729. The Infirmary had grown greatly since that time; its patients came from a very wide area, including the Hebrides, Orkney, and Shetland, a large part of the north and east of Scotland, and the area immediately round the Lothians and southern border. The visit of His Royal Highness would draw attention to the need for extension in view of the long waiting list, the requirements of the nursing staff, and other matters. The sum required for this purpose would be at least £500,000. The Prince, in reply, remarked that the Edinburgh Infirmary was the largest voluntarily supported hospital in Great Britain, and he would be very happy if his visit helped to draw attention to its needs and to the appeal which was about to be made. He sincerely hoped that the funds required for the extension would be obtained.

Care of the Blind in Scotland.

The annual conference of the Scottish National Federation of Institutions and Societies for the Blind was held in Perth on June 12th and 13th, and was attended by about eighty delegates. A civic welcome was accorded by the federation by Lord Provost Dempster, who referred to the beneficent work carried on by the various institutions and societies affiliated to the federation, especially in providing blind persons with the means of working and earning something to maintain their spirit of independence. Parliament was now rightly providing pensions for the blind, and had conferred powers on local authorities to promote their welfare, but the need for these societies was as great as ever in order to supply the personal and human touch. An address was delivered by Colonel Robert Forbes, Government inspector, on the training of the blind. He stated that in recent years, as the result of the advance of medical preventive and remedial measures, the number of blind children had shown a very marked decline. In the past the tendency in training had been to overlook the fact that the psychological outlook of the person born blind was entirely different from that of a person who had a conception of a visible world. It was a debated question whether the blind child should be educated in a day class or whether he should reside and be taught in an institution reserved for the blind. In either case there was an absolute necessity to detect as early as possible any particular aptitude or ability, and to develop any special bent.

Glasgow Radium Institute.

The Glasgow and West of Scotland Radium Institute at Garnethill was formally opened on June 10th by Principal R. S. Rait of Glasgow University, under the chairmanship of Sir John M. Macleod, who expressed regret at the absence of Sir George T. Beatson, to whose vision, wisdom, and patience, he said, the hospital owed its present position. Principal Rait, in declaring the institute open, referred to the great excitement caused about the year 1893 by the discovery first of x rays and then of radium. He mentioned that before the war radium cost about £36,000 for one gram, but, unlike other commodities, the price had fallen since the war owing to the discovery of deposits on the Congo; one gram could now be obtained for about £12,000. He quoted a statement that radium could undoubtedly remove cancerous growths without injury to the surrounding healthy tissue, and thought that this represented an enormous advance in the alleviation of human suffering. It justified the spending of a large amount of money in procuring radium, and also in training people in its use. The practical application of the properties of radium required the most delicate and sustained study; this was not understood by many people. As the result of the munificent gift of Lady Burrell it had been possible to establish this radium institute; those in charge of the cancer hospital did not intend to confine the radium to the use of the hospital itself, but to share it with other hospitals. An important scheme of a radium institute with a radium officer, beds for patients, and staff of trained nurses had been formulated, and it was a matter for pride that this had been done before the Government scheme was elaborated by the National Radium Commission. There was still room, however, for the operation of such an independent foundation, and the Commission admitted that the work in Glasgow was in no way antagonistic, but that the two undertakings could cooperate. The Duchess of Montrose afterwards performed the opening ceremony of the nurses' home at the institute, and mentioned, as an example of the increased work of the Glasgow Cancer Hospital, that about thirty-four years ago, when the first extension to the hospital was opened, about eighty or ninety patients were treated annually in the wards, whereas last year the figure was 479.

New Edinburgh Medical Officer of Health.

At a meeting of the town council of Edinburgh on June 10th, Dr. John Guy was elected medical officer of health for the city in succession to Dr. William Robertson, retired. After some discussion it had been resolved to advertise the post, and twenty-one applications were received. The two names finally submitted to the town council were those of Dr. Guy and Dr. William George Clark, at present senior assistant to the medical officer of health, Glasgow. On a division Dr. Guy received 41 votes and Dr. Clark 21. Dr. Guy, prior to his appointment, acted for several years as deputy medical officer of health for Edinburgh, and was tuberculosis officer for the city. He graduated M.B., C.M. at Glasgow in 1894, proceeded M.D. in 1900, and received the diploma in public health from Cambridge University in 1899. He became a Fellow of the Royal College of Physicians of Edinburgh in 1917. After holding the posts of county tuberculosis officer in Gloucester and medical superintendent of the Bridge of Weir Sanatorium, he went to Edinburgh about sixteen years ago as tuberculosis officer. He has contributed to numerous periodicals dealing especially with the treatment and administrative control of tuberculosis.

Edinburgh Hospital for Crippled Children.

A garden fête in aid of the Edinburgh Hospital for Crippled Children was held on May 31st at Craigiehall, Cramond Bridge, near Edinburgh. Sir David Wallace occupied the chair, and the fête was opened by Lady Rosebery, who remarked that although several hospitals existed in England for the treatment and cure of crippled children, no provision of this nature had so far been made in Scotland. The general infirmaries and children's hospitals were often unable to keep such children for a sufficient time, and their home conditions were very often such that a relapse was almost inevitable. The hospital soon to be completed near Edinburgh would specialize in these cases, and would provide educational and gymnastic facilities during the long period that it would be necessary to keep these children. The hospital would have seventy-five beds to start with, but provision was being made for another seventy-five beds, and although the bulk of the money required for the hospital had been received a great deal would be necessary for its extension. The sum raised by the fête amounted to over £900.

Measles Epidemic in Edinburgh.

A severe epidemic of measles has recently occurred in Edinburgh. The disease has been generally spread over the city; during the fortnight ended June 7th, 1,041 cases were notified, with twenty-one deaths. Since March of this year there have been approximately 8,000 cases, involving about 4,000 families.

England and Wales.

Sir William Morris's Gift to Oxford.

THE munificent gift to the University and city of Oxford made recently by Sir William Morris was gratefully accepted for the University in a unanimous vote in congregation on Tuesday, June 10th. This gift—as wise in conception as it will be far-reaching in its consequences—consists of a large area of land adjoining the Radcliffe Infirmary, known as the Observatory site, and the Observatory and other buildings on the site which have been purchased by Sir William Morris. It is to be administered by trustees, the land being for the use of the hospital, and the existing buildings for the purposes of the School of Medicine. To the Radcliffe Infirmary the possession of this land will be an inestimable boon. It solves a problem which had recently become one of great urgency, and of the utmost anxiety to the hospital, shut in as it is on a comparatively narrow strip of ground between Somerville College and the Observatory grounds; for the hospital now serves the greater part of the three counties of Berks, Bucks, and Oxon, as well as the city and neighbourhood, and the need for new wards and other extensions had become extreme. But there was nowhere to put them, with adequate regard to modern hospital requirements and future needs, short of moving the whole hospital to an entirely new site in the suburbs—a plan which had been under serious consideration. The Observatory ground will meet all possible needs for very many years to come, and practically in perpetuity. Its possession, together with that of the Observatory buildings

(which are besides of considerable architectural interest), will also make possible the initiation of a scheme which has been present to the minds of members of the Faculty of Medicine for some years past, and must become prominent in the future development of the School of Medicine, for the provision of full facilities for clinical research, and the further linking up of the University departments of medical science, with their unrivalled opportunities for research, with the clinical investigation of disease at the bedside. This scheme is still in an embryonic stage, but Sir William Morris's generous and far-sighted gift lends it fresh vitality, and brings it into the field of living possibilities. It will now only await a free supply of that form of nourishment which alone is adequate to pass successfully through its period of gestation. Large new benefactions must, however, be obtained before this can be achieved, and the scheme carried on to full maturity.

Papworth Village Settlement.

An encouraging account of the work of the clinic for women and children run in connexion with the *Papworth Village Settlement* appears in the medical director's report for 1929. The number of children now under supervision is 173, and of these 44 are of pre-school age, 36 are over 14 years of age, and have employment in Cambridge or are continuing their education there, and 93 are of school age and attend the village school. Medical examinations during the year under review have confirmed the previous experience that the children born in the village have remained free from tuberculosis. In selected cases a series of tests have been carried out with Hamburger's ointment, consisting of ground tubercle bacilli, by means of which, according to Hamburger, 100 per cent. positive results may be obtained in tuberculous children. The test has been applied only to children who had been exposed to infection, but gave, contrary to expectation, a negative tuberculin reaction as indicated by Moro's tuberculin ointment test. In this way evidence "of having met the bacillus," though not of actual tuberculosis, has been found in two children not born in the village. Both these children are maintaining excellent health. Although, as in previous years, the Papworth Settlement has been remarkably free from infectious diseases, the outbreak of streptococcal tonsillitis reported last year has been troublesome and has persisted throughout the winter. During 1927 the effect of small doses of iodine given in the form of iodized chocolates was tried in a group of eight children with enlarged tonsils thought to be due to hypothyroidism. During the year under review nine children, in whom there was some indication for tonsillectomy other than simple enlargement of the tonsils, were selected as a control, and subjected to tonsillectomy. As a result it appeared that, though in most cases the general condition improved considerably, the procedure had certain disadvantages. Among the sequels have been troublesome middle ear disease and prolonged febrile attacks with involvement of glands. It is noteworthy that microscopical examination, which was carried out on all the removed tonsillar tissue, has shown no evidence of tuberculous infection.

New Milk Laboratories opened in London.

An extension of the milk research laboratories of United Dairies, Ltd., at Willesden, was opened by Sir Andrew Balfour on June 16th, on the occasion of a luncheon presided over by Mr. J. H. Maggs, chairman of the company, and attended by many hygienists and medical officers of health. Before the opening a tour was made of the laboratories, which are well equipped with every means of investigation into milk problems. The routine work consists of the examination of milk samples by microscopical, chemical, bacteriological, and physical means, the cleanliness, freshness, quality, and purity of the milk being thus determined. It was stated that more than a million samples, taken at every stage of the milk's progress, are tested every year, a number several times greater than the total of samples taken by the public health authorities throughout Great Britain. This work goes on in thirty laboratories, nine of which are in London. At the new Willesden laboratories, in addition to the routine tests, research work is carried on with the object of still further improving the milk supply. One item of the most recent equipment is a lantern through which milk samples, magnified 225,000 times, are projected on to a screen. The routine of the actual pasteurizing process, which is undergone by the milk at the London depots before dispatch for distribution, is controlled from the research laboratory, and any peculiar result is carefully investigated. To demonstrate the advances which have been made in milk production, the firm staged an exhibit of the primitive tests carried out by the dairy trade twenty years ago—tests made by visual observation, and carried out irregularly and by unqualified people. To-day more than a hundred analytical and bacteriological chemists are in the employment of the company.

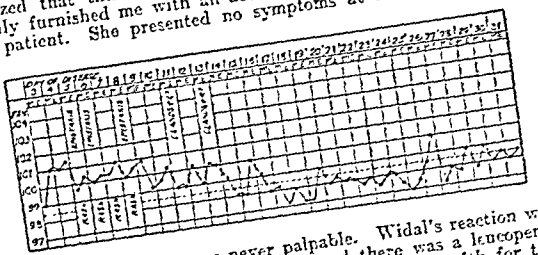
Sir Andrew Balfour welcomed the members of the public health services, whose presence, he said, testified to the co-operation which existed between science and industry. Happily the time was rapidly disappearing when medical officers of health regarded traders as crafty schemers endeavouring to take advantage of the public, while traders looked upon the M.O.H. in the same light as the burglar looked upon the detective. The United Dairies had been leaders in an industry which had made greater advances in the past decade than any other branch of industry connected with food supply. Beginning with the cow and the cowshed, they had aided the work of the M.O.H. in rural districts by influencing the cleaner production of milk through the introduction of clean milk competitions and young farmers' clubs. They had also developed new and hygienic methods of transport in the shape of large glass-lined tanks, and in London they had established a chain of pasteurizing plants, which were most efficient, and which contained the very latest in the way of equipment and machinery. They had also done a great work by transferring practically the whole milk supply of the metropolis from the open can to the hygienic sterile bottle. He also referred to the help which the United Dairies had given in popularizing the results of research, and in helping research itself. They had seconded the teaching of the public health schools by supplying exhibits of a highly technical nature, which enabled students to obtain a thorough grasp of the whole subject of milk from the cow to the consumer. The fine laboratories opened that day, with their highly trained staff, were yet another effort on the part of this enlightened company to give the best service they could to the milk-consuming public and to raise the milk industry to the position it deserved. When one remembered experiences long ago in general practice in connexion with enlarged cervical glands, which in the majority of cases were due to infection by bovine tuberculosis, one could not but rejoice at these developments. Other speeches were made by Mr. Ben Davies and Mr. P. B. Tustin of United Dairies, and Dr. J. B. Howell, president of the Society of Medical Officers of Health, responded for the visitors.

St. Marylebone Rheumatism Centre.

In a brief report on the activities of the St. Marylebone Children's Rheumatism Supervisory Centre during 1929 the medical director states that, owing to closer co-operation with the London County Council's schools, more children are now being referred to the centre for advice and supervision, and that parents of children who have been treated at the centre are also responsible for making the work better known. The London County Council has voted a grant to the centre in recognition of the value of its work to the schools in the Marylebone area. The centre has no intention of competing with institutions which exist for the purpose of treating definitely developed rheumatism in children and adults; its primary aim is to inquire into the nature of the constitution of rheumatic children. *Each child is given a complete clinical examination* when it is first brought to the centre, and further observations are made on its subsequent attendances. Biochemical investigations during the period under review tend to confirm the view previously arrived at that the most common abnormality of chemical constitution in the rheumatic subject is faulty metabolism of calcium, phosphorus, magnesium, and sulphur. Two biochemical groups can be differentiated: one, which as a rule does not suffer

from cardiac rheumatism, presenting either no deviation of the acid-base equilibrium of the body, or a slight deviation to the alkaline side; the other, to which belong cases of cardiac rheumatism, showing a deviation of the acid-base equilibrium to the acid side. In a very large proportion of the children investigated up to date no evidence has been found of an infective process, and the medical director makes the suggestion that most of the subjective symptoms can be accounted for by metabolic abnormalities alone. Recent studies have suggested the possibility that lack of balance or inadequacy of the glands of internal secretion may be one of the primary causes of rheumatism, and at the centre an attempt is being made to interpret both clinical and biochemical findings in terms of endocrine functions.

Bath's Summer Season.



The recognized season at Bath is autumn to spring, but in order to extend the usefulness of the spa during the summer, and in view of the many to whom "taking the waters" at any other time of the year is impracticable, the spa committee of the corporation has arranged to issue a "summer cure ticket." For an inclusive sum of three guineas this ticket admits its holder to a three weeks' course at the baths during the months from June to September, as well as to all the publicly provided amenities of the spa. The ticket can be used only under medical advice, but it is available up to a maximum of six treatments a week for any bath or douche or other form of application at the bathing establishment, prescribed by the physician before the course is begun. The bathing establishment, as readers of the *Journal* know from many descriptions in these columns, has now a very large and comprehensive installation, and includes numerous electrical and other accessory methods. The holder of the ticket will find the Pump Room open to him, as well as the gardens by the Avon, where the waters are also served for drinking, and where band concerts and other entertainments are continually being given. The hotels, by arranging special inclusive terms for the three weeks' period, are co-operating in the effort, the motive of which is to divert to the West of England some whose summer fancies might stray to Continental resorts. Inquiries should be addressed to Mr. John Hatton, the spa director.

Correspondence.

GLANDULAR FEVER.

SIR,—In their interesting account of a series of cases of glandular fever reported in the *British Medical Journal* of June 7th, Drs. Evans and Robb emphasize the difficulty of making a diagnosis when the case is a solitary one. The following case, which I think must have been one of this kind, seems of sufficient interest to record.

On April 18th a hospital nurse began to have headache, backache, and general malaise. She was admitted to my ward on April 20th (temperature 100°, pulse 84, respiration 20). She seemed rather dull and drowsy, but there was nothing definite. On the evening of April 22nd she had epistaxis, and again next morning. Typhoid was suspected and apparently confirmed by finding a typical rash on the abdomen. The only uncertain features were its early appearance, the rather large amount of it, and the wide area over which it extended. Spots were seen not only on the abdomen, but on the chest and back, and a few on the upper arms and thighs. The abdomen was not palpable, nor was its dullness increased. The abdomen was not distended. The tongue was not typical. Leucocytes 6,300 per c.mm. The blood was negative to the typhoid group. Blood culture was sterile. During the next few days her general condition remained much the same, the temperature being between 99.5° and 101.4°. Fresh crops of spots appeared daily for the next few days, the older ones fading. On April 24th there was more epistaxis. On April 25th the diazo-reaction of the urine was negative. The spleen was still not palpable; there was no distension. The bowels were normal. On the strength of the rash, the unexplained fever, and the epistaxis together with the leucopenia, I thought this was one of the typhoid group, and yet it was not altogether like typhoid. On April 28th, the eleventh day of her illness, she complained of pain and stiffness in the left side of the neck, and a chain of small hard tender glands was palpable behind the sterno-mastoid. Two days later similar painful glands were felt in the right side of the neck. The fever continued. The tonsils were rather large, but there was no sore throat, and a swab was negative. On April 30th Dr. Egerton Williams of the City Fever Hospital saw her with me, and offered to take her into the observation wards there. On May 10th Dr. Tidy's letter appeared in the *British Medical Journal* calling attention to an epidemic of glandular fever in London, and I then realized that this might be such a case. Dr. Williams has kindly furnished me with an account of the further history of the patient. She presented no symptoms at all suggestive of

typhoid. The spleen was never palpable. Widal's reaction was again negative in the fourth week, and there was a leucopenia of 5,000. The temperature fell to normal on May 4th for two days, then went up again; it became normal once more on May 7th for six days, and on May 13th rose again for four days; it finally came down on May 17th—that is, on the thirtieth day of her illness. She was discharged ten days later.

This case does not conform fully to glandular fever; there was no lymphocytosis and no splenic enlargement. Whether there was actually a relative lymphocytosis is unfortunately not known, as at the time the first count was made the question of glandular fever had not arisen, and the record of the differential count made later is missing. The absence of splenic enlargement tells equally against each diagnosis. On the other hand, there is much in favour of it being glandular fever: (1) the definite appearance of enlarged lymphatic glands on both sides of the neck on the eleventh and following days of a continued fever; (2) the duration of the fever, with intervals of normal temperature during the third and fourth weeks; (3) the absence of the typical course of typhoid, and of a positive Widal reaction even during the fourth week. As regards the rash one can only say that typhoid-like rashes have been recorded in cases of glandular fever, and that in this case it seemed to be just a little too obvious and too early for typhoid. Finally, the case occurred about the time of the known epidemic in London. The three charts in Evans and Robb's paper are dated as beginning on March 28th, and April 6th and 22nd respectively. This case began on April 18th.—I am, etc.,

ARTHUR J. HALL.

Sheffield, June 10th.

MATERNAL MORTALITY.

SIR,—In reply to Dr. Jellett's letter in the *Journal* of May 24th (p. 974) I would like to make it perfectly clear that the remarks I quoted about asepsis had no reference whatsoever to the Rotunda Hospital, but to midwifery in general. The two quotations were taken from different parts of the book, with a full stop between. No one was more surprised than I was that Dr. Jellett should have taken this interpretation; no one has more admiration than I have for the methods and teaching of the Rotunda Hospital. With regard to rectal examinations, I am glad to know that they do not meet with Dr. Jellett's approval, and that my impression from reading the considerable discussion allotted to them in his book was erroneous.—I am, etc.,

A. LOUISE MCILROY.

Obstetric and Gynaecological Unit, Royal Free Hospital, June 11th.

ANTIMALARIA MEASURES.

SIR,—The malaria-mosquito controversy has been further illuminated by Colonel Gill in the correspondence columns of the *Journal* (April 12th). The subject is of vital interest to all public health workers in Malaya. It is owing to the patient research and indomitable perseverance of Sir Malcolm Watson and other workers that a firm foundation has been laid for a system of antimalaria control without which this country could never have reached its present stage of development.

If claims of successes were unsubstantiated by practical results, is it likely that the great majority of large rubber estates and other commercial organizations, working *within* malaria danger zones in Malaya, would have voluntarily adopted measures of specific anti-larval control by means of oiling or drainage, as the only known means of keeping the incidence of malaria within reasonable limits? And what of Italy, where anti-larval measures, suitably applied, have helped to free large tracts of country from the havoc of malaria? Yet those who cling to the belief that active measures should be taken, wherever possible, to reduce malaria by breaking a certain link in the chain of this disease are now to be classified as complaisant heretics whose existence "exercises a baneful influence on the prosecution of antimalaria measures."

Those who have followed Sir Malcolm Watson's teaching are aware that he is no less a believer in research than in the need for immediate action. In a striking paragraph on page 217 of his book *The Prevention of Malaria*, he clearly visualizes the time when "drainage schemes may become methods of the past."

Surely there is no need to define an issue by the aggressive attribute of "old" and "new." We all will welcome and are striving for some new means of combating malaria, but such is the urgency of our problem that tropical sanitarians throughout the Empire should join forces to enlighten lay administrators as to what can be accomplished by the use of present knowledge and what *may* be possible when research has paved the way for a great discovery. In Malaya, happily, research and the practical application of existing knowledge go hand in hand.—I am, etc.,

J. W. SCHARFF, M.D., D.P.H.,
D.T.M. and H.

Singapore, May 18th.

SIR,—I should like to be permitted to reply briefly and collectively to the criticisms evoked by my letter in your issue of April 12th. These criticisms have mainly been directed against (1) the distinction made between the old and modern schools of malariologists, (2) the employment of the term "unsubstantiated" in connexion with the successes claimed by the old school, and (3) the alleged neglect of anti-larva measures by the modern school.

If the use of the term "old school" is a source of offence I gladly withdraw it. There is, indeed, as Sir Ronald Ross remarks, only one school, whose members are all actuated by one motive alone—to render the malaria-ridden world a healthier place for man to dwell in. Such differences of opinion as do exist refer to the relative value of the methods of attaining the object in view; one school, whose views are at present dominant, maintaining that anti-mosquito, and more particularly anti-larva *measures, constitute the first and last word in malaria* control; whilst others hold that this view is not only not in accord with modern scientific knowledge, but that existing methods of mosquito control do not provide, for financial and administrative reasons, a practicable means of controlling malaria among the teeming millions of the Tropics. Time alone will prove which of these schools will survive; in the meantime the difference of opinion may be regarded as a healthy sign, provided the protagonists on each side keep an open mind and do not obscure the issue by indulging in personal recriminations.

In regard to the use of the term "unsubstantiated," my contention was not that the claims made by the mosquito enthusiasts were unsubstantial, but that in many cases they had not been substantiated. To illustrate my point it is only necessary to refer to Sir Malcolm Watson's letter in your issue of February 8th, in which he states that in Malaya his methods have resulted in "a saving of tens of thousands of lives (over 58,000 in the city of Singapore alone since 1911), and an enormous, indeed incalculable, saving of money." No malariologist would hesitate to advocate, and no Government would fail to adopt, any scheme which is capable of yielding such magnificent results, but before doing so they have a right to expect that a full and detailed account of the methods employed both in the execution of the scheme and in the statistical appraisement of its results should be published. I appeal to Sir Malcolm Watson to provide this information, for if his contention is correct he will have provided a complete answer to those who hold that anti-larva measures are financially and administratively impracticable in respect of the vast rural areas of India, where 90 per cent. of the population dwell. But having regard to our own studies of the malaria problem and of our special knowledge of local conditions we first require to be convinced, and, as scientific men, we are not prepared to act on bare assertions from whatever source they may emanate.

It is perhaps unnecessary to say anything more in regard to the alleged hostility to anti-larva measures. A reference to my letter will show that it contains no statement that anti-mosquito or anti-larva measures are useless or of little value. The point it was desired to make was that in the present state of knowledge little or no progress in dealing with the problem of rural malaria in the Tropics is possible, except on a small scale and in a few favoured localities, with the aid of anti-larva measures *alone*, and that it would appear to be unwise, in carrying out anti-malaria measures in these areas, to ignore the part played by economic conditions and by human carriers. This statement does not imply that anti-larva measures are of little value—in the case of urban malaria in India this method is indeed usually the method of choice—but it was made to emphasize the view that no instructed malariologist who has to deal with malaria under a wide variety of conditions should confine his attention solely to one of the several factors concerned in the endemiology of the disease and direct attention solely to one factor concerned in its causation. Unfortunately many malariologists are entomologists, either by profession or by choice, and it is consequently only natural that they should stress that aspect of the problem with which they are peculiarly fitted to deal.—I am, etc.,

C. A. GILL,
Lieutenant-Colonel I.M.S.

Simla, June 4th.

"DISCARDED METHODS" IN LARYNGOLOGY.

SHOULD SHORTENING OF THE ELONGATED UVULA, AND THE ORIGINAL LARYNGOSCOPIC METHOD FOR LARYNGEAL WORK BE DISCARDED?

SIR,—In a small work on modern treatment of diseases of the throat, nose, and ear, recently reviewed in your columns (*Journal*, June 14th, p. 1099), I find under the heading of "Discarded methods" the "complete or partial removal of the uvula" and the "indirect (original laryngoscopic) method" for "laryngeal work."

It will be a sorry day for certain patients when the shortening of the uvula is discarded. We know that an inordinately long uvula may be present without any symptoms, and we know that a cough may coexist with a long uvula and be due to some other cause altogether, but we know—or, at least, I know—that in many cases a cough is caused by an elongated uvula and is removed at once, and often for all, by the shortening of that appendage.

As regards the discarding of the original laryngoscopic or *indirect method in favour of the direct endoscopic* method for laryngeal work, the latter may be much easier for the operator, but it is certainly not easier for the patient, unless under a general anaesthetic. For the most common innocent new growth in the larynx—namely, the so-called "fibroma" on the edge of a vocal cord at or near the junction of the anterior and middle thirds—the specialist ought to be able to effect the removal by means of the ordinary forehead and laryngeal mirrors and laryngeal forceps, without the paraphernalia of the endoscopic apparatus, and without general anaesthesia. This applies still more to the electro-cauterization of tuberculous ulcers in the larynx, as it may have to be repeated on several occasions.—I am, etc.,

JAMES DUNDAS-GRANT.

London, June 16th.

TREATMENT OF RECTAL PROLAPSE.

SIR,—I am glad to find that Mr. Ian Fraser, in his article on prolapse of the rectum in children (June 17th, p. 1047), supports my advocacy of treatment by injection. In my article in the *British Medical Journal* of April 14th, 1928 (p. 633), the case was instanced of a man of 66, suffering from bronchitis and double hernia in addition to a large prolapse of ten years' duration, who was cured of the prolapse by half a dozen injections, and who reported no recurrence over a year later. If subsequent correspondence be any criterion, the article aroused very considerable interest in the method, which does not require the use of an anaesthetic, nor necessitate the patient leaving off work during treatment, and is applicable to any age. Since its adoption by my staffs I have not required to operate on a case of prolapse in any of the hospitals to which I am attached.—I am, etc.,

J. MACEWEN.

Glasgow, June 11th.

DRUG TREATMENT OF MEASLES.

SIR,—We read with interest Dr. J. I. Collier's article (June 14th, p. 1093) on the use of amidopyrin in measles, as we used the drug in all cases treated last winter. All patients were seen daily at least for the first five days, and daily notes of all cases seen are kept. One or two cases were mild, several were severe. In one case the diagnosis was doubtful; it may have been German measles. The following six cases are taken at random.

Case 1.—Aged 15; seen twenty-four hours after rash appeared; temperature 102°; cough; fine rales all over chest. Temperature normal in twenty-four hours; cough much less, and rales gone. Well in three days, out in eight days.

Case 2.—Aged 4; had whooping-cough recently; temperature 104°; cough; rash out. Temperature normal in twenty-four hours, and remained normal. Well in five days.

Case 3.—Aged 48; had slight bronchitis for months, and had pyrexia for three days before being seen. Temperature 103.8°; very bad rash, and bronchitis. Temperature fell to 99° in twenty-four hours, but there was an evening rise to 100° for three nights. Was well in seven days, and then had less bronchitis than before the measles. An expectorant mixture was taken from the fourth to the eighth day.

Case 4.—Aged 8; temperature 103.8°; rash just appearing; cough troublesome. Temperature was 98.8° in twenty-four hours, but rose to 100° by evening, remaining normal after the second day. The child was very ill for twelve hours and had diarrhoea. Refused to take prescribed dosage on the second day. A younger sister died of measles at home (treatment unknown). Patient was in a boarding school.

Case 5.—Aged 3; temperature 104°; rash out; cough troublesome. Temperature fell in twelve hours, and remained down. Cough was almost gone in twenty-four hours. One dose of a linctus was taken.

Case 6.—Aged 5; just recovered from bronchitis. Temperature 104°; cough; rash out; rather ill. Temperature fell to 99° in thirty-six hours, and general condition was good. Only one dose of amidopyrin had been given in the first fourteen hours.

The drug appears to have an almost specific action. There were no complications, and the catarrhal symptoms cleared up with surprising rapidity. There was no need to give a linctus to relieve the cough; this subsided with the temperature. Drug treatment other than amidopyrin appeared unnecessary, and practically all cases could have been allowed up on the fourth day. The dose given was 5 grains four-hourly until the temperature was normal, then 5 grains thrice daily for two days. In Case 5 this appeared rather too much; the patient slept for fourteen to fifteen hours. In two cases a haemorrhagic rash may have been due, in part or wholly, to the drug used.

The treatment would appear worthy of trial on a large scale.—We are, etc.,

G. H. URQUHART, F.R.C.S.Ed.
A. H. WINCHESTER, F.R.C.S.Ed.

St Annes-on-the-Sea, June 15th.

SIR,—I was much interested to read in last week's *British Medical Journal* the results of the treatment of measles with amidopyrin. For some years now I have been treating measles with the powder consisting of acetosalicylic acid 5 grains, compound ipecacuanha powder 2½ grains, and phenacetin 2½ grains, made for me by Messrs. Richardson of Leicester, and of which I claim to be one of the originators. When discussing with the late Sir Archdall Reid of Portsmouth the marvellous effects of these powders, if given in sufficient doses and early, in acute lobar pneumonia in children, he advised me to try them in measles and mumps. His exact words in his letter to me were: "In measles you will get amazing results, the last six cases I treated being well in forty-eight hours, and mumps in one day, though in the latter the swelling persisted for a short while." I think it is due to his memory that these facts should be known.—I am, etc.,

H. J. CLUTTERBUCK.

Llanelly, June 16th.

INSTRUMENTAL ROTATION IN THE OCCIPITO-POSTERIOR CASE.

SIR,—In the *British Medical Journal* for June 7th Dr. Douglas Miller says that forceps rotation for occipito-posterior cases "demands a high degree of manipulative skill, and . . . should be attempted only by the expert." Your leading article on the subject adds that "the modern obstetric forceps is an unsuitable instrument for rotating an occipito-posterior head," which reads like an editorial announcement that the discussion is now closed. Fortunately Professor John Hay, in his splendid Mackenzie Memorial Lecture (printed in the same issue), pleads that "the general practitioner must become one of the team, his position frankly realized, and his co-operation welcomed."

On more than one occasion during the past twenty years I, a general practitioner, have dared to interrupt these recurrent studies of the occipito-posterior problem with a plea for the use of forceps to rotate. Oftener I have remained silent. No specialist has urged the merits of the method; some have turned it down; one grimly pictured its potentialities for fatal torsion of the foetal neck. I think it was then that the open minds closed with a snap. But wait.

Just recently I learned that the professor in whose class some thirty-six or thirty-seven years ago I received the hint to rotate an occipito-posterior head with forceps never himself reckoned the method safe enough to use. He confessed the fact to his successor in the chair. But his class (in my day) never sensed a doubt. So in faith, happily ignorant of apprehensions, reckoning naught of twisted necks, unsuspicious of the suitability of "modern obstetric forceps," never pausing to take stock of my "manipulative skill," I have gone on all these years applying the lesson. And not once have I seen cause to repent.

The manœuvre is simplicity itself. There is no feat in obstetrics so essential in general practice, easier to perform, more effective. Deep chloroform anaesthesia is desirable throughout. You diagnose the position of the head, lay your blades as squarely to its sides as possible, lock the instrument, *and keep it locked*, then (in a pause between pains, and gently) push the foetus back towards the uterus until its head feels free. Now, still gentle, you give the forceps a half turn (like a key in a lock) and proceed to deliver. The original instruction—to bring the head down until it is fixed and then withdraw the reversed forceps and apply them again—is unnecessary. More, it may do harm. Heads can revert too easily. Thus in all but exceptional cases it is safer and easier not to unlock the forceps. The facility with which delivery can be effected with them in this manner is a shock to one's notions about the parts and the art—but a salutary shock, for modern obstetrics tends to become paralysed with exuberant theory.—I am, etc.,

ROBERT WATSON.

Belfast, June 8th.

LOCAL RESISTANCE TO INFECTION.

SIR,—I was interested in Dr. H. W. Webber's letter (June 14th, p. 1112) concerning the high resistance to infection in the perianal region. The mouth, at the other end of the alimentary tract, is equally exposed to infection. Here also the local immunity is very high. Surgical operations and the ordinary extraction of teeth leave raw and damaged tissues bathed with saliva having countless micro-organisms in suspension, yet healing takes place rapidly without infection spreading. In the process of evolution this local immunity has no doubt been a necessary condition for our survival.—I am, etc.,

R. ERNEST RIX, M.R.C.S., L.D.S.

London, W.1, June 14th.

CONTROLLABLE SPINAL ANAESTHESIA.

SIR,—I was interested in Mr. R. A. Grant's article (June 14th, p. 1088) giving an account of his experience with spinocain. Most surgeons will agree that stovaine is now quite out of date for spinal anaesthesia. Its alleged advantages—complete relaxation and small amount of bleeding—are probably due to low blood pressure and collapse. Its use was given up in this hospital in February, 1928; since then spinal anaesthesia has been used on 1,300 occasions. The drug first used to replace stovaine was neocaine, supplied by Corbière, but after a time May and Baker supplied a preparation which they first called ethocain, and later planocain. I have always understood that these drugs had the same formula as novocain. In each case the drug was supplied dry in a sterile ampoule, and was dissolved in cerebro-spinal fluid before injection. The dose was usually 0.1 gram. The results have been very satisfactory, and the number of cases in which the condition of the patient gave any cause for anxiety has been very small.

There can be no doubt that novocain is an enormous improvement on stovaine, but Dr. Pitkin is not entitled to credit for this, as might be assumed from Mr. Grant's statement that planocain "is really strychnine-free spinocain." I tried spinocain on one case, but the resulting anaesthesia was not quite sufficient, and as excellent results were being obtained with planocain I was not encouraged to persevere.—I am, etc.,

HENRY H. MACWILLIAM.

Walton Infirmary, Liverpool, June 16th.

ANAESTHETICS FOR SHORT OPERATIONS.

SIR,—Dr. R. W. Hornabrook (*Journal*, May 31st, p. 1022) expresses views on anaesthetics which are not in accordance with the usual experience of the majority of anaesthetists. They are not necessarily wrong because of that, but it is a special reason why statements so contrary to the generally accepted belief should be backed up by facts to support them. I do not want to write a long letter, and should not have written at all but for one sentence, although I do not agree with many other statements in Dr. Hornabrook's letter. The particular assertion I object to, because it is entirely wrong, is: "Nitrous oxide, and nitrous oxide and oxygen, have many advantages, but they are largely overrated." I say they are very much underrated; if they were used more extensively we should not get the wretched tale of chloroform fatalities following teeth extraction and the opening of small abscesses which we do at present. It is only necessary to look up the standard works on anaesthesia to appreciate the fact that they all agree that nitrous oxide with oxygen is the safest anaesthetic, the chief objection to its use being the cost and cumbersome apparatus.

In a recent number of the *Dental Journal* Dr. de Caux gives an account of 24,000 cases of gas and oxygen anaesthesia, including many major operations, without a fatality. He adds that if trouble is experienced with this anaesthetic it is invariably the workman who is at fault, and not the tools. I have seen men who tried to screw a nut on a bolt cross-threaded, and then complained that it would not fit. I have also seen men trying to give gas and oxygen who were incapable of holding a mask on a patient's face without allowing about two inches gap for air to leak, and then complaining that the gas and apparatus were all defective. Ross and Fairlie, in their textbook, state at page 93: "The lack of toxic properties in nitrous oxide gas, and the rapidity with which it is eliminated, give it a tremendous advantage over chloroform and ether. . . . Even in normal subjects the after-sickness and malaise are definitely less than with other anaesthetics." In his book on anaesthetics Blomfield writes (p. 390): "So far as short operations are concerned, universal record and opinion put nitrous oxide with air or oxygen in the first place of all general anaesthetics as regards safety." Hewitt records 20,000 cases with no death. In Gwathmey's *Anaesthesia* (p. 325) we read: "Nitrous oxide with oxygen is easily the safest anaesthetic known. It is almost impossible to kill normal animals with this combination."

I take it that safety is with most of us the first consideration in the choice of an anaesthetic. I know it is with me, but there are also other reasons for preferring nitrous oxide and oxygen which I will not go into now.—I am, etc.,

Doncaster, June 5th. E. J. CHAMBERS.

CANCER-PRODUCING SUBSTANCES.

SIR,—The discovery in the Research Institute of the Cancer Hospital (*British Medical Journal*, June 7th, p. 1044) that a certain cancer-producing substance shows a blue-violet fluorescence which becomes very intense in a beam of ultra-violet light, and the hope expressed by Dr. Kennaway that it might be possible to state if products contain cancer-producing substances by analysing their spectrum, suggest ways of improving our knowledge of cancer. The most striking among many facts should be that a very high temperature appears to be necessary for the production of most of the cancer-producing substances; it has therefore been assumed that living tissue is capable of a synthesis at low temperatures which can only be produced outside the body by the use of great heat.

In this connexion it must be remembered that electronic action in many cases is able to promote the same synthesis as great heat. On metallic surfaces, for instance, rapidly moving electrons are present with a kinetic energy high enough to transpose molecules to one of their higher energy states (in this way catalysis may be explained). Such molecules are very active, and may return to their normal state by liberating energy in the form of radiation.

Now it is believed that radiation of one wave-length furthers cancer, just as another wave-length destroys cancer. In the same way cancer-producing substances may promote cancer by radiation directly or through intermediary products formed. The increase of cancer may therefore be a result of some of the methods used in the modern chemical industry. The hardening of fats, for instance, takes place in the presence of highly dispersed catalysts, which may not be quite removed before the fat is mixed into margarine. A minute quantity of substances able to cause radiation may thereby be introduced into the body, and the development of cancer be thereby promoted. That natural food seems to keep down the spread of cancer is in accordance with this view. Hence it should be of the highest importance to co-operate with food manufacturers to obtain products free from the possible cancer-producing substances which chemical treatment may be able to incorporate with them.—I am, etc.,

Copenhagen, June 14th. J. E. NYROP, B.Sc.

MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—During the next two weeks the Society of Members of the Royal College of Surgeons of England will circularize all Members resident in the United Kingdom and Ireland soliciting a postal vote on the question of some representation of the Members on the Council of their College. Having regard to the great amount of work and expense entailed thereby it is earnestly hoped that all Members will respond promptly, and thus make their views known.—I am, etc.,

London, W.1, June 10th. ERNEST E. WARE.

FINANCE AND RESPONSIBILITY.

SIR,—National health insurance is so much better than nothing at all, or than clubs of the baser sort, that almost everyone in our profession accepts it without question. When a desert blossoms into 9s. capitation fees the plodding ass rejoices. But animals that feed with a snatching movement uproot the tender plant. Sir Walter Kinnear has warned us!

Inherent in the Act is this vice: that the finance is divorced from the responsibility. The patient has paid by his stamps, and does not see why he should not get his own back. The married woman in industry, who "could

do with a month at home"; the domestic who is "always tired" and wants "a real rest"; the subchronic valetudinarian workman who is unfit to work for twenty-six weeks, but recovers miraculously on the twenty-seventh—all such as these are weeds that yearly grow ranker. There are half-reasons why they should go sick; there are half-reasons why the doctor should give them a note. A financial bias is needed to stiffen native honesty—witness the return to work after the twenty-sixth week.

The doctor who says, "Do you want a note?" exceeds his duty. "If so desired by the insured person" the note is to be given. The note-profferer feeds with a snatching movement. Why are the funds getting less and less adequate? Is there really more sickness year by year? Is it not that our national self-reliance is sapped by this vicious divorce of finance from responsibility?

The B.M.A. Proposals for a General Medical Service, beautifully woven into a closely knitted fabric, may all, I fear, fray out on pulling the financial thread. In seventy-one splendid paragraphs the Council builds up its scheme, and then in No. 72 refers the foundation of the whole structure to "bodies which are much more competent to deal with the financial aspects." You might as well say: "Let the architect design the façade; it is the duty of an engineer to plan the construction."

The finance of a scheme is integral. When you separate means from ends things go wrong. In a really national system the patient pays in the long run, and proportionately to his means he ought to pay in the short run, and to know that he pays and what he pays. On any other footing he will come in time to ask more than any professional panel can provide or any sick fund bear.—I am, etc.,

LIONEL JAS. PICTON.

Holmes Chapel, Cheshire, June 12th.

A PANEL OF EXPERT TRANSLATORS.

SIR,—I venture to bring to your notice a project which is likely to be of interest to your readers—the formation by the Association of Special Libraries and Information Bureaux of a panel of expert translators.

Those who require the services of a translator often experience difficulty in finding one who has both a knowledge of the language and also of the special subject concerned, and the difficulty increases where the language is uncommon and the subject highly technical. Proficiency in the language is not enough. To afford specialized service the translator must have not only a good knowledge of the language, but a really close acquaintance with the subject he has to translate—for example, the law, metallurgy, medicine, architecture, management, or whatever the subject may be.

With the object of overcoming this difficulty, which has been brought to their notice continually, the council of the association recently appointed a committee consisting of Dr. S. C. Bradford, librarian, the Science Library; Allan Gomme, librarian, the Patent Office; Dr. R. S. Hutton, director, British Non-Ferrous Metals Research Association; Miss A. L. Lawrence, M.B.E., M.A., LL.B., intelligence officer, British Medical Association; Brigadier-General Magnus Mowat, C.B.E., M.Inst.C.E., M.I.Mech.E., secretary, Institution of Mechanical Engineers; and E. J. Robson, M.A., librarian, Institute of Agricultural Engineering, to prepare a scheme for establishing a panel of translators having both linguistic and technical qualifications, the part taken by the association being to act as a connecting link between the translator and the user. Names of approved qualified persons are now being registered under the scheme adopted, and those who are interested, in either capacity, are invited to write for particulars to the secretary, Association of Special Libraries and Information Bureaux, 26, Bedford Square, London, W.C.1.

Whilst the panel is intended to consist primarily of approved individual translators, it is hoped that commercial translating bureaux, which may partly or wholly function in the field of specialized subjects, will apply for registration if they are prepared to satisfy the association of their ability to offer such high-grade service.—I am, etc.,

J. J. THOMSON,
President.

June 16th

Obituary.

GEORGE NEIL STEWART, M.D., D.Sc., LL.D.Ed.,

Professor of Experimental Medicine, Western Reserve University, Cleveland.

WE regret to learn of the death, on May 28th, after a long illness, at Cleveland, U.S.A., of Dr. G. N. Stewart, professor of experimental medicine, and formerly professor of physiology, in the Western Reserve University, and clinical physiologist to Lakeside Hospital, Cleveland.

George Neil Stewart was a student of Edinburgh University, where he graduated M.A. with honours in mathematics and D.Sc. in 1889. He obtained the M.B. degree in 1890, and proceeded M.D. in 1891, winning the gold medal for his graduation thesis. He was also a D.P.H. of Cambridge. After post-graduate study in Berlin he became senior demonstrator of physiology in the Owens College of Manchester, and was for some years on the staff of the Department of Physiology at Aberdeen. He also held for some years the George Henry Lewis student-ship at Cambridge University. Before his appointment to the chair of physiology at Cleveland, Dr. Stewart was for a number of years professor of physiology in the University of Chicago. His *Manual of Physiology*, first published in 1896, went through no fewer than eight editions. The author's purpose was to interweave formal exposition with practical work, according to a programme he had followed for some years in teaching physiology to medical students on the other side of the Atlantic. He was also the author of a series of papers on the "Liberation of epinephrin from the adrenals," published in the *Journal of Pharmacology and Experimental Therapeutics*. In 1922 the University of Edinburgh conferred on him the honorary degree of LL.D.

The funeral was held at the University Chapel in Cleveland on May 31st. Professor Stewart's remains were cremated and the ashes taken to Toronto, where his wife and four children live.

A. A. SCOT SKIRVING, C.M.G., M.B., C.M., F.R.C.S.Ed.,

Late Senior Surgeon, Edinburgh Royal Infirmary.

THE death took place, on June 14th, at his residence in Rothesay Place, Edinburgh, of Mr. Archibald Adam Scot Skirving, lately senior surgeon of the Royal Infirmary, Edinburgh. His health for a few years past had been unsatisfactory, so that about two years ago he resigned his appointment at the Royal Infirmary, although he had not completed his full period of office in that institution.

He was born in 1869, a member of a well-known Edinburgh family, his great-grandfather, Adam Skirving, having been well known as the author of the Jacobite song "Hi! Johnny Cope." After receiving his early education at Edinburgh Academy and Cheltenham College, he took up the study of medicine at Edinburgh University, graduating M.B., C.M. in 1893. After graduation he acted as resident surgeon to the late Professor John Chiene, and subsequently pursued a course of study in Paris and Berlin. He took the Conjoint qualification in London in 1895, and joined the Royal College of Surgeons, Edinburgh, as a Fellow in 1897. For a time he held the post of demonstrator in anatomy at Surgeons' Hall, Edinburgh, and of surgeon to the New Town Dispensary, afterwards being appointed surgeon to Leith Hospital, and later surgeon to the Edinburgh Royal Infirmary. He was for many years a lecturer on systematic surgery in the School of Medicine of the Royal Colleges at Edinburgh, where he always succeeded in attracting a large class of students. He was the author of a treatise on *Surgical Applied Anatomy*, and of the article on the "Neck" in the *Encyclopædia Medica*, and contributed numerous articles to periodical surgical literature, such as "Extensive injury to brain by Mau-er bullet," in the *Edinburgh Hospital Reports*, vol. vii, and a paper on "An unusual symptom in secondary syphilis" in the *British Medical Journal* for 1901.

During the South African war Mr. Scot Skirving went to South Africa as the chief surgeon attached to the Imperial Yeomanry Field Hospital, and his services there

were mentioned in dispatches and received recognition by the award of the C.M.G. During the great war Mr. Skirving again acted as a surgeon, attached, in the first place, to the Second Scottish General Hospital, and afterwards to the Bangour War Hospital; and for about a year he served in France as a temporary major in the British Expeditionary Force. His interests outside medicine were many. As a student he was senior president of the Students' Representative Council at Edinburgh University, and he played Rugby football for the Edinburgh Academicals. He was a keen sportsman, his recreations being fishing, shooting, and motoring, and he constantly took a great interest in the work and sports of his old school, the Edinburgh Academy. Here he was the leading figure in connexion with the preparation of such things as the school register, the war memorial, and the war register.

Possessed of a generous, open, and kindly disposition, he was universally popular, and greatly beloved by his medical colleagues. His cheery, bright, and amusing temperament made him a much sought raconteur at medical gatherings, and his charming personality, as well as his surgical skill, will be greatly missed by a wide circle of colleagues and friends. Mr. Skirving is survived by a widow.

DR. THOMAS TREFFRY COCKILL, who died on June 12th, after some months of confinement to bed, was the son of the late Rev. W. R. C. Cockill, and was born in India in 1866. He entered Middlesex Hospital in 1887, where he gained an entrance scholarship, the Broderip scholarship, and the Lyell gold medal. He qualified as M.R.C.S., L.R.C.P. in 1891. After service as house-physician at the Middlesex and the North Staffordshire Infirmary he entered into general practice at Hanley, and was appointed assistant physician to the North Staffordshire Infirmary and Eye Hospital. Later he removed to Richmond, Surrey. Dr. F. Jupe, assistant medical officer to King Edward VII Sanatorium, Midhurst, writes: Commencing with a gastric ulcer Cockill was dogged by ill health, which would have kept any ordinary man in an armchair. But he believed in spending himself for others and, although obliged to relinquish general practice, he filled his years with work. In 1916, although very much a C3 man, he consented to set Dr. Bardswell free for war work by acting as medical superintendent of King Edward VII Sanatorium, and only those who knew him most intimately at that time realized at what cost to himself and his devoted wife he managed to carry on during the following three years. Really in need of treatment himself, he sacrificed his own health to give hope and the ideals of a new life to his patients. Since 1920 Dr. Cockill acted as secretary to the Surrey Local Medical and Panel Committee, in which capacity his broad-mindedness and sense of humour has made his counsel invaluable. Lately, in addition, he undertook the work of the secretaryship of the Surrey Branch of the British Medical Association. As an old patient and colleague of his I owe more than I can ever tell to his example of cheerfulness and unselfishness. His legion of friends have lost one whose inspiration has made life a far richer thing for all of us.

The death of DR. JOHN CHARLES GRANT of West Boldon in the county of Durham (writes Professor Grey Turner) removes certainly the most popular figure from that village and from the neighbouring colliery. His father was an old Crimean veteran, and the son, whose death is so much deplored, was born sixty-seven years ago in the house where he died on June 2nd. As a young man, he helped his father in the practice, but he was rather late in qualifying, which explains how he and I came to be fellow students for a time. After the death of his father, Charles Grant carried on and largely extended the old practice almost up to the day that he died. His activities can best be described by saying that he was always "on his rounds," for I never knew anyone so continuously occupied in professional duties. He was most devoted to his practice and to the people among whom he lived and laboured. He did most of his work on a bicycle, except on those rare occasions when he allowed himself the luxury of a hire from "Mark," who for many years was the local cabman, and afterwards motor proprietor. Grant was always courteous and dignified, and with an attractive old-world bearing, and although he lived among the people of the large colliery district where he held sway, he always remained the same, and was universally looked up to and respected. He had a great sense of the dignity of the profession, and worthily upheld that ideal often under difficult and trying circumstances. Though he sent numbers of patients to the infirmary, he always politely acknowledged every communication sent by the members of the staff who saw his cases, so that we were all very familiar with his bold penmanship. There is no doubt that his devotion to work shortened his life, for, in spite of his continuous day and night exertions, he could scarcely ever be persuaded to take a day off, much less a holiday; but though his death in harness is so much regretted, I feel sure that he would not have wished it otherwise. No name will ever be better remembered in Boldon, and none ever mentioned with more respect. His funeral was a remarkable demonstration of affection. The little church of St. Nicholas, where he had worshipped during the whole of his lifetime, and where he was remembered as a choir boy, was packed to overflowing during the beautiful service preceding interment, and the mourners at the cemetery made a great throng, who came out of affection for their lost friend.

The death took place on May 30th, at his residence, Redhurst, Dunoon, Argyllshire, of DR. JOHN BANKS, who had attained the age of 81 years. Dr. Banks graduated M.B., C.M. at Glasgow in 1872, and was one of the few remaining medical practitioners who studied under Lister in that medical school. He commenced practice in Dunoon in 1877, and shortly afterwards obtained the position of medical officer of health for the burgh, taking the D.P.H. in 1889. He held this post for over fifty years, retiring in January of the present year, when he was a recipient of a presentation from his patients. Dr. Banks was a widower, and leaves a family of two sons and two daughters.

The Services.

HONORARY SURGEON TO THE KING.

MAJOR-GENERAL W. R. Blackwell, C.M.G., late R.A.M.C., has been appointed honorary surgeon to the King, vice Major-General H. P. W. Barrow, C.B., C.M.G., D.S.O., late R.A.M.C.(ret.).

Medico-Legal.

ATTENDING WORK WITH SMALL-POX.

DOROTHY BEECH was fined at the Lambeth Police Court, on June 11th, for having, on April 17th, travelled across London to her employment while suffering from small-pox. The summons alleged that she had wilfully exposed herself without taking proper precautions against spreading the disease. In pleading ignorance, the defendant stated that she had been vaccinated twice and considered herself immune from infection. As evidence that she was aware of her condition, Mr. Roberts, who prosecuted on behalf of the Lambeth Borough Council, referred to certain statements made by the defendant to Dr. Ashley Thompson, the borough medical officer of health.

SPECTACLES FOR A SCHOOLBOY.

ON June 13th Henry Ford was summoned, at the Bromley Police Court, Kent, by the National Society for the Prevention of Cruelty to Children for neglecting to provide optical treatment for his son, aged 12, when ordered to do so by the school medical authority. He was fined 40s., and ordered to pay £5 5s. costs. It appeared from the evidence that the school medical officer ordered spectacles for the boy in January, but the father, resenting outside interference, declined to get them for four months, although the society was prepared to pay the cost if necessary. The prosecution was undertaken on the ground that permanent injury to the boy's eyesight might have resulted from this delay.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT reassembled on June 17th. On that day and subsequently the House of Commons was in committee on the Finance Bill. The Ministry of Labour Estimate was also debated. An amendment made by the House of Lords to the Mental Treatment Bill was set down for consideration by the House of Commons on June 20th. This amendment deleted the proposed audit of accounts in licensed houses.

In the House of Lords, on June 17th, the Illegitimate Children (Scotland) Bill was read a second time.

R.A.M.C. Officers.

In the House of Commons, on June 6th, Dr. FREMANTLE asked whether Mr. Shaw knew that, whereas combatant officers' pensions had increased in value since the war, the pensions of officers of the R.A.M.C. had decreased. He drew attention to the fact that the pension earned by a major R.A.M.C. at twenty years' service was now £368 per annum, which was worth little more than half the pre-war rate of £365 per annum fixed in the reorganization of 1902. He asked Mr. Shaw whether it was proposed to reduce or increase this pension next year, and whether the Minister could give an undertaking that the maximum pension for a lieutenant-colonel of the R.A.M.C., attainable after twenty-eight years' service, would not be further reduced from its present amount of £558

Mr SHAW replied that the retired pay of majors and lieutenant-colonels of the R.A.M.C. in receipt of post-war scales was subject, like that of other officers, to revision next year in the light of the cost of living figure. He could not say what the result of that revision would be.

Dr. FREMANTLE asked if the pensions of lieutenant-colonels had been reduced this year to £1 a day, and would be further reduced next year. He asked further whether this would not affect the recruiting of young medical officers.

Mr SHAW said the rule with regard to the cost of living applied to all officers of the Army without distinction. He promised to inform Dr. Fremantle from time to time of the results of the consideration.

Dr. FREMANTLE also asked Mr. Shaw if he was aware that the officer strength of the Royal Army Medical Corps was made up for requirements, resulting in the employment of civilian practitioners and the re-employment of retired officers, all of whom did home service only, and that the average period of foreign service undertaken by regular officers of the R.A.M.C. had increased in consequence; and whether, seeing that this prospect was bound adversely to affect the recruitment of young medical officers to the service, he would consider how these conditions of service could be improved.

Mr. SHAW said he had under his consideration at the present time the whole question of the supply of officers for the R.A.M.C. Last year special steps were taken to render conditions of service in the Corps more attractive. Certain concessions had been made regarding the counting, for purposes of promotion, increase of pay and pension, by officers appointed to permanent commission in the Corps, of temporary service in the Corps, or of time spent in a civil hospital appointment. The Army Council were also in touch with civil hospitals at the present time to see whether arrangements could be made by which R.A.M.C. officers might be enabled to secure experience in civil hospital appointments.

Dr. FREMANTLE inquired whether Mr. Shaw knew the question of recruitment of medical officers would arise again that month, and presumably the Minister would not be able to get a supply of officers for the Corps unless these matters were remedied.

Mr Shaw did not reply.

Silicosis.

Mr. HOPKIN asked on June 5th, about the case of a man of Gorslas, Carmarthenshire, who was certified in June, 1929, to be suffering from silicosis, was a few weeks later declared by the medical referee not to be suffering from silicosis, and was proved by post-mortem examination in April, 1930, to have died from silicosis.

Mr. CLYNES replied that the facts appeared to be as stated by Mr Hopkin. Owing to the condition known as anthracosis the diagnosis of the disease in this case during lifetime would be of particular difficulty. He added that the case afforded an illustration of the need for improved medical arrangements by setting up of an expert medical board for the whole country, as recommended by the Departmental Committee. He sought to obtain the necessary powers for this purpose in the Workmen's Compensation (Silicosis) Bill now before the House. He hoped this would be proceeded with immediately after the recess, and as soon as the bill became law steps would be taken to establish the new medical organization with the least possible delay.

Asked whether he would include anthracosis in the bill, Mr. CLYNES said he must have notice of that question.

In a further reply to Mr. Hopkin, on June 5th, Mr. CLYNES said the investigation of silicosis in the Cross Hands district of Carmarthenshire by the Mines Department was proving much more laborious than had been anticipated. He could not say whether the report would be published when received.

Cancer of the Bladder in Aniline Workers.—In an answer to Mr. Philip Oliver, on June 5th, Mr. CLYNES said it had been decided that, to assist in the investigation by the London Cancer Hospital into the incidence of cancer of the bladder among workers in aniline factories, the Factory Department of the Home Office should co-operate by tracing the exact occupations of persons who had died of cancer of the bladder. The Registrar-General was extracting information, and his first return was practically ready. The research was complex and difficult, and Mr. Clynes could not forecast when conclusive results might be expected.

An Antivivisection Mare's-nest.—Mr. FREEMAN asked Mr. Clynes, on June 5th, whether experiments upon living animals had been conducted at the physiological laboratory, Cambridge, by Mr. B. H. C. Matthews; the purpose of which was to measure pain; what species of animals were used in this investigation; and under what certificates the experiments were conducted. Mr. CLYNES said he had inquired into the circumstances. The purpose of the experiments was not to measure pain but to measure electrical impulses, and they were not performed on living animals. No licence was necessary for this, and Mr. Matthews did not hold one.

Notes in Brief.

During the year ended March 31st, 1930, the Government paid the following grants to voluntary societies in England and Wales: maternity and child welfare, including grants for the training of midwives and health visitors, £264,354; welfare of the blind, £124,007; treatment of tuberculosis (paid to the Welsh National Memorial Association), £112,196.

Whether treatment of national health insurance patients by ultra-violet rays is within the scope of medical benefit has to be decided, Mr. Greenwood says, in any particular case in accordance with Article 43 of the Medical Benefit Regulations.

Mr. Greenwood states that beds are not specially set aside in institutions under the Board of Control for cases receiving psychotherapeutic treatment, though such treatment is available in the normal course at many of these institutions.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Schorstein Research Fellowship.

THE Board of the Faculty of Medicine has elected Patrick Corbett Mallam, M.A., B.M., of University College, to a Schorstein Research Fellowship.

UNIVERSITY OF LONDON.

A READERSHIP in biochemistry, tenable at the London School of Hygiene and Tropical Medicine, is to be instituted in accordance with the Regulations on University Titles (*Calendar*, 1929-30, pp. 214-224).

GUY'S HOSPITAL MEDICAL SCHOOL.

Applications for the Gull studentship in pathology and allied subjects, of the annual value of £250, tenable for three years, must be received by the Dean, Guy's Hospital Medical School, London Bridge, S.E.1, by June 28th. The studentship is open to candidates under 35 years of age who have studied in the Medical School of Guy's Hospital.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

CH.M.—R. V. Cooke.

FINAL M.B., CH.B., PART I (*including Forensic Medicine and Toxicology*).—K. P. Beaubrun, L. C. Holland. (*In Materia Medica, Pharmacy, Pharmacology and Therapeutics, and Pathology (completing examination)*: A. J. B. Miall. PART II.—*J. F. Coates (distinction in Medicine and Obstetrics), *G. F. Langley (distinction in Medicine and Public Health), H. T. G. Cornfield, R. D. Jones, R. A. Lattey, R. P. Lucas, H. M. Strover. *In Group I (completing examination)*: R. M. Norman.

DIPLOMA IN PUBLIC HEALTH, PART II (*completing examination*).—W. W. S. Sharpe. * Second-class honours.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council of the Royal College of Surgeons was held on June 12th, when Lord Moynihan, the President, was in the chair.

Fellowship.

It was reported that of the 134 candidates who presented themselves for the Final Fellowship examination, 44 were approved, including one candidate who had not yet complied with the regulations. The Diploma of Fellowship was granted to the following 43 candidates:

C. L. Kindersley, A. G. Hayward, Philippa P. Martin, H. R. Bishworth, L. A. Bennett, A. E. Smith, T. E. Cawthorne, T. S. Donovan, A. E. De Chazal, F. J. T. Foenander, J. G. Milner, J. G. Y. Bell, A. C. Copley, J. R. Bateliffe, J. C. Ross, T. H. Sellors, G. H. Livingstone, H. Lyon-Campbell Wood, H. O. Hanvell, A. C. Perrit, R. Rutherford, M. L. Ashmawi, A. M. A. Moore, J. Fesser, A. E. Taylor, K. H. Watkins, H. H. Stewart, D. W. Currie, V. Srinivasan, H. Tayler, T. Giblin, J. G. Sandrey, R. H. Hedley, S. J. Mehta, S. Lal, W. D. Bedford, N. L. Formby, R. Grainger, V. J. Kinsella, E. I. A. Macdonald, J. Mark, R. J. C. Maxwell, H. M. Stewart.

Membership.

Diplomas of Membership were granted to Mabel E. Grace, Joyce MacInnes, Ruth Milne, and Helen E. Rodway, who had previously passed the final examinations of the Examining Board in England and had now complied with the regulations.

Examiners.

Mr. C. Max Page, surgeon to St. Thomas's Hospital, was elected a member of the Court of Examiners for a period of five years, in the vacancy occasioned by the retirement of Mr. Graham Simpson (Sheffield).

The following examiners were elected for the ensuing year:

Dental Surgery (Surgical Section): L. B. Rawling, John Murray, H. S. Clogg, C. E. Shuttock, T. P. Legg, C. P. G. Wakeley, Russell J. Howard, Gwynne Williams.

Fellowship (Anatomy): P. N. Blake Odgers, William Wright, J. E. S. Frazer, J. Basil Hume. *(Physiology)*: H. E. Roaf, C. Lovatt Evans, R. J. S. McDowall, J. Mellanby.

Under the Conjoint Board:

Elementary Biology: J. P. Hill, T. J. Evans. *Anatomy*: R. B. Green, W. E. Le Gros Clark, H. A. Harris. *Physiology*: E. B. Verney, H. Hartridge. *Midwifery*: C. White, Trevor B. Davies, A. W. Bourne, S. Forsdike. *Diploma in Public Health (Part I)*: J. W. H. Eyre; *(Part II)*: C. W. Hutt. *Diploma in Tropical Medicine and Hygiene (Pathology and Tropical Medicine)*: David Harvey; *(Tropical Medicine and Surgery)*: G. C. Low. *Diploma in Ophthalmic Medicine and Surgery (Part I)*: H. Willoughby Lyle W. S. Duke Elder; *(Part II)*: R. Affleck Greeves. *Diploma in Psychological Medicine*: J. G. Greenfield. *Diploma in Laryngology and Otology (Part I)*: W. M. Mollison, Norman Patterson; *(Part II)*: W. G. Howarth. *Diploma in Gynaecology and Obstetrics*: J. D. Barris.

Hunterian Professor.

Dr. Harold Dew, Professor of Surgery, Sydney University, was elected a Hunterian Professor for the ensuing year, and will deliver a lecture on "Hydatid disease—some interesting complications," on Thursday, July 10th, at 2.45 p.m.

Primary Fellowship Examination in Canada.

It was decided to proceed with the arrangements for holding the Primary Examination in Anatomy and Physiology for the Fellowship in Canada at Montreal, and Professors William Wright and C. Lovatt Evans were appointed to conduct the examination.

University of Brussels and School of Medicine.

Sir H. J. Waring was appointed to represent the College at the ceremonies of the inauguration of the buildings of the University of Brussels and of the School of Medicine on June 23rd, 24th, and 25th, 1930.

Primary Fellowship.

At the recent primary examination for the Fellowship 158 candidates presented themselves, of whom the following 54 were approved:

S. Ahmad, G. L. Alexander, D. R. Bharucha, R. W. Billington, V. G. Borgaonkar, G. H. Brandis, M. Coleman, T. G. B. Crawford, A. W. Cubitt, M. P. Ellis, R. E. Fernando, D. I. Fitzpatrick, G. H. V. Froggatt, E. Galinsky, P. H. R. Ghey, B. Gilbert, A. El S. Handousa, J. B. Harman, B. P. Harris, G. J. Hollis, J. F. Jarvis, A. N. Jones, K. D. Keele, T. King, R. Lal, J. M. Leggate, A. H. London, F. R. Leonard, H. G. Letcher, A. L. Light, S. N. Lytle, E. G. MacMahon, K. M. Masani, Mary H. Mayeur, D. M. Mitchell, N. St. C. Mulhearn, F. G. Murphy, J. H. North, J. O'Donnell, J. Penry, G. Qvist, F. C. T. Rawle, R. V. Rickard, L. N. Ross, J. E. Semple, E. J. Smith, B. R. Sworn, G. R. A. Syme, G. G. Talbot, W. H. Taudy, Lilian E. Tracey, E. N. Wardle, J. C. F. L. Williamson, I. Zieve.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE Royal Faculty of Physicians and Surgeons of Glasgow has decided to confer the distinction of its Honorary Fellowship upon the three following members of the medical profession: Robert Muir, M.D., Professor of Pathology in the University of Glasgow; William Loudon Reid, M.D., Lecturer on Midwifery and Gynaecology in the Anderson College of Medicine, Glasgow; and Lieut.-Colonel Laurence Austine Waddell, C.B., C.I.E., M.B., LL.D., Professor of Chemistry and Pathology at Calcutta Medical College.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

AT the monthly business meeting held on June 13th, the following candidates were admitted Licentiates and Members of the College: H. F. Moore, S. C. Chatterjee, L. Rodrigues.

The representatives of the College on the Irish Medical Council and on the General Medical Council reported on the recent proceedings of those bodies.

SOCIETY OF APOTHECARIES OF LONDON.

THE Court of Assistants of the Society of Apothecaries of London has appointed Mr. Reginald Silby Lewis, M.A., LL.B.Cantab., to be Registrar to the Society.

LONDON INTERCOLLEGIATE SCHOLARSHIPS BOARD.

THE following medical scholarships have been awarded on the results of the Board's examinations:—*University College Medical School*: (£30 per annum for three years) to H. A. Catley. *King's College*: Warneford scholarship (£30 per annum for four years) to C. W. Dixon and H. J. Stammers; Sambrooke scholarship (£30 per annum for three years) to J. V. Dacie.

ROCKEFELLER MEDICAL FELLOWSHIPS.

THE Medical Research Council, on behalf of the Rockefeller Foundation, has made the following awards of Travelling Fellowships for the academic year 1930-31. These Fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine and surgery, and who are likely to profit by a period of work at a chosen centre in America or, in special cases, in Europe, before taking up positions for higher teaching or research in the British Isles.

RUSSELL CLAUDE BROCK, F.R.C.S., Guy's Hospital, London.
FRANK BURNET BYROM, M.D.Lond., M.R.C.P., London Hospital.
DESMOND CURRAN, M.B.Cantab., M.R.C.P., Hospital for Epilepsy and Paralysis, Maida Vale, London.
ALAN AIRD MONCRIEFF, M.D.Lond., M.R.C.P., Hospital for Sick Children, Great Ormond Street, London.
ARTHUR SPENCER PATERSON, B.A.Oxon, M.B.Ed., Assistant Physician, Royal Glasgow Mental Hospital.
CHARLES CADY UNGLEY, M.D.Durh., M.R.C.P., Royal Victoria Infirmary, Newcastle-on-Tyne.

Dr. Moncrieff's Fellowship is tenable at Hamburg; the others at centres in the United States. Mr. Brock and Dr. Curran have been appointed on modified conditions while receiving emoluments from other sources.

Medical News.

THE annual dinner of the Royal Medico-Psychological Association will be held in Christ Church Hall, Oxford, on Wednesday, July 2nd, at 7.30 p.m.

THE annual dinner of the St. Bartholomew's Hospital Ninth Decennial Contemporary Club will be held at the Langham Hotel, Portland Place, W., on Wednesday, July 2nd, at 8 o'clock, with Dr. R. J. Morris in the chair.

A SPECIAL meeting of the Orthopaedic Section of the Royal Society of Medicine will be held at St. Vincent's Orthopaedic Hospital, Haste Hill, Eastcote, near Pinner, on Saturday, June 28th, at 3 p.m. There will be a short demonstration of methods by the gymnastic staff and an inspection of the hospital and cases under treatment. Tea will be provided.

THE inaugural meeting of the Paddington Medical Society was held on June 10th at the Paddington Town Hall. There was a large attendance. The object of the society is to discuss all modern developments in medicine in so far as they affect the medical practitioner, and to promote and safeguard the efficiency and independence of the medical practitioner. Membership is open to all practitioners residing or practising in the metropolitan borough of Paddington. Meetings will be held once a month. Intending members should communicate with the honorary secretary, Dr. J. Cohen, 23, Westbourne Park Road, W.2.

AT a conference to be held at L'Hydro Institut Hélio-Marin d'Ostende on July 6th papers will be read on the symptomatology, meningeal forms, and serotherapy of poliomyelitis, and on the present state of vaccine therapy in the treatment of acute pulmonary infections. In connexion with the conference there will be a banquet and a concert. Medical men and women wishing to be present are asked to notify Dr. Ed. Delcroix, 94, Boulevard Van Iseghem, Ostende, before June 30th.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that Dr. W. J. Adie will give two lectures on diseases of the nervous system, to candidates for the M.R.C.P. examination on June 24th and 27th, at 8.30 p.m., at the Medical Society of London; fees 10s. 6d. per lecture, payable at the lecture hall. On June 23rd, at 2.15 p.m., Dr. J. Strickland Goodall will give a demonstration at the National Hospital for Diseases of the Heart in the out-patients' department. On June 25th, at 1.30 p.m., Mr. R. Y. Paton will demonstrate at the Royal National Orthopaedic Hospital. Both of these demonstrations are free. Courses in progress are an intensive course in tropical diseases, continuing until July 4th; the second week of an intensive course in medicine and surgery at the Prince of Wales's General Hospital; the second week of a morning and/or afternoon course at the Chelsea Hospital for Women; and an afternoon course at the Blackfriars Skin Hospital. Proportionate fees will be accepted for these courses. From June 30th to July 5th an all-day course will be given by the staff of St. Mark's Hospital for Diseases of the Rectum; fee £3 3s. Attention is directed to an intensive course in maternity and child welfare to be held under the auspices of the Maternity and Child Welfare Group of the Society of Medical Officers of Health and the Fellowship of Medicine. The full programme may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1, to whom application should be made about the above-mentioned courses.

DR. E. GRAHAM LITTLE, M.P., has been appointed to represent the University of London at the tenth session of the Journées Médicales de 1930, to be held at Brussels from June 28th to July 2nd.

A POST-GRADUATE course of instruction in maternity and child welfare arranged, under the auspices of the Maternity and Child Welfare Group of the Society of Medical Officers of Health and the Fellowship of Medicine, will be given in London from June 30th to July 5th inclusive. The fee for the course (ten shillings) should be sent to the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

AN international medical post-graduate course, with special reference to balneology and balneotherapy, will be held in Carlsbad from September 14th to 20th. Addresses will be delivered by clinicians and scientists from various European countries and the United States of America. Further details may be obtained from the secretary of the course, Dr. Edgar Ganz, Carlsbad, Czechoslovakia.

THE National Hospital, Queen Square, announces that, beginning on July 2nd, the out-patient department will be open from 1 p.m. on Wednesdays. Under this new arrangement out-patients will be seen each afternoon except Saturday.

AT the invitation of the baths directorate of Pistany Spa, Czechoslovakia, a three weeks' tour for medical practitioners and others will be held in August and September. The itinerary includes a week-end at Oberammergau, with seats for the Passion Play; three days in Vienna, visiting various medical centres; day visits to Munich, Prague, and Linz; and a week at Pistany Spa, where fishing, golf, and tennis are available. The cost of the tour is inclusive, and substantial reductions have been arranged for the party. Further details may be obtained from the Pistany Spa Representation, 136, Regent Street, W.1.

MISS M. E. DAVIES, matron-in-chief, Ministry of Pensions Nursing Service, retired from that post on June 16th, on completing eleven years' service. Owing to reduction in the hospital work of the Ministry it has been decided that the post of matron-in-chief shall lapse. The post of principal matron will continue to be held by Miss H. G. Palin, who will discharge the necessary inspectorial functions in addition to her duties as matron of Queen Mary's (Roehampton) Hospital.

THE Council of Epsom College will shortly elect a girl to a St. Anne's Scholarship of £120 a year. Candidates must be of the age of 9 years, and not over 12 years of age on July 30th next, and must be orphan daughters of medical men who have been for not less than five years in independent practice in England or Wales. Application must be made by July 3rd, on a form to be obtained from the secretary of the College, at 49, Bedford Square, W.C.1.

AT the meeting of the Central Midwives Board for England and Wales on June 5th a letter was read from the Ministry of Health referring to a suggestion from the Board that, in view of the fact that Poor Law institutions were now under the control of local supervising authorities, the approval of training of all midwives should be identical. The reply was to the effect that the Minister did not consider there were any sufficient reasons for reconsideration of the present position. The Board agreed that all training schools, whether attached to hospitals or otherwise, should, as regards approval, be dealt with on a uniform basis. A letter was read from the clerk of the Buckinghamshire County Council informing the Board that the Council was prepared to support the Joint Committee of Associations in its opposition to any legislation involving the transference of the control of the profession of midwifery from an independent body like the Central Midwives Board to a Government Department, and any interference with the rules of the Central Midwives Board.

THE report for 1929-30 of the Birmingham Women's Welfare Centre, affiliated to the Society for the Provision of Birth Control Clinics, records a steady increase in the number of attendances since the clinic was opened in 1927, and the result of an investigation from which it was learned that about 84 per cent. of the patients attending the centre had previously experimented with contraceptive methods on their own account. The committee, in order to obtain detailed information about the value of the methods taught at the centre, has decided to follow up the early cases, starting with the first 150, and towards the expenses of this investigation it has received a grant from the Birth Control Investigation Committee.

MESSRS. H. K. LEWIS AND CO., LTD., have published charts for recording the curve in sugar tolerance examinations. Each chart has printed on it the average normal curve, and it is therefore easy to plot the results of a particular examination, and to determine at once the degree of any departure from the normal. The price of these charts ranges from twenty-five for 2s. to 1,000 for 50s.

THE forty-eighth annual dinner of the West London Medico-Chirurgical Society was held at the Trocadero Restaurant on June 12th, when the president, Dr. J. F. Halls Dally, was supported by a large and representative gathering. In his speech proposing prosperity to the society, Lord Moynihan of Leeds, P.R.C.S., took occasion to administer a genial rebuke to medical London for its provincial outlook. Nevertheless, he agreed that London, for all its backwardness, had taught undergraduates almost all it knew, and had instilled into them the principles of right conduct. Its besetting fault had been the lack of a proper post-graduate ideal and sense of responsibility towards those whom it had trained in its schools and those who came to London from other places at home and abroad. Lord Moynihan hoped, however, that when the British Post-Graduate Hospital and Medical School arose London would take its place as a great centre of medical thought and inspiration. An indispensable part of this scheme was the setting up of a hostel where graduates could get into social contact during their courses. The whole scheme rested on four pillars—a hospital, a school, a hostel, and a centre for surgical research, which he hoped might be established at Charles Darwin's home. The chairman, in replying to the toast, touched briefly on the history of the West London Medico-Chirurgical Society, its debt to Charles Keetley, and its pride in the distinguished men who had received its gold medal or delivered its Cavendish Lectures. The health of the guests and kindred societies was proposed by Dr. A. Knyvett Gordon, and responded to by Sir Edward Macartney (Agent-General for Queensland), Dr. P. Montague Smith (president of the Harveian Society of London), and Major Hugh Wakefield. The chairman's health was proposed by Sir Dennis Herbert, and Dr. Halls Dally replied.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9361, 9362, 9363, and 9364* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

DISCONTINUANCE OF PEPTONE TREATMENT.

"H. A. C." writes: I have treated a patient successfully for migraine with peptone I grain twice daily, and should be glad of suggestions as to discontinuing the treatment, which has been maintained for six months. Should the peptone be stopped suddenly or gradually?

TRICHINOSIS.

DR. JOSEPH LLOYD (Swansea) writes: I have under my care in this district a family of five persons who have been stricken very ill—all having been in good health previously—with signs and symptoms of trichinosis. The illness started with gastro-intestinal symptoms, followed by very severe oedema of the face, high fever, muscular pains, especially affecting the biceps and gastrocnemii muscles, weakness, and prostration. There is marked eosinophilia. I should be grateful for information about any similar cases existing at the moment in other parts of the country. So far it appears that the illness followed a meal of boiled ham taken a few weeks ago.

*** In the *British Medical Journal* of April 5th, 1930 (p. 630), Drs. Herzberg and Vitenson reported a case occurring in London, and on May 10th (p. 832) Dr. Jean Murray reported an outbreak of trichinosis in a bacon factory at Bradford-on-Avon.

TREATMENT OF PRURITUS ANI.

MR. C. D'OYLY GRANGE, F.R.C.S. (Harrogate), writes in reply to "Cerous" (June 7th, p. 1080): I have had excellent results with the subcutaneous injection of "A.B.A." as described by W. B. Gabriel in the *British Medical Journal* of June 15th, 1929 (p. 1070). If there is much moisture I combine this with the application of calamine, either in the form of powder or in a very thick lotion.

*** Mr. Gabriel stated that "A.B.A.," prepared for him by Messrs. Allen and Hanburys, is a 3 per cent. solution of anæsthesin with benzyl alcohol 5 per cent. and ether 10 per cent. in sterilized olive oil.

DR. FREDK. WM. ALEXANDER (Teddington) writes: About two years ago a septuagenarian medical man asked me if I could do anything for his pruritus ani, from which he had suffered for years and tried every known remedy without relief. For a period of about ten minutes I applied on the outside of the anus high-frequency electricity by means of an ordinary glass vacuum electrode kept close to the surrounding parts and moved around. From the first application the effect was striking, and an absolute cure resulted after a few treatments. Was it the ozone in this instance?

DR. THOMAS I. MILLS (York) suggests the use at bedtime of a salve containing ol. menth. pip. 5 per cent. in Lassar's paste.

PROTECTION AGAINST SUNBURN AND MIDGE BITES.

PROFESSOR J. A. NIXON (Bristol) sends the following replies to questions by Dr. Ivan B. McCann and "Perplexed" in the *Journal* of June 7th (pp. 1079, 1080):

Prevention of Sunburn.—The best protecting substance is quinine, either in the form of a lotion (1 per cent.) or an ointment (5 per cent.). As it is difficult to introduce quinine into an ointment, I give a formula which I have found effective in the mountains:

Quinine acid hydrochloride (dissolve 1 in 2 of water)	5
Anhydrous wool fat	40
Oil of lavender	1
Soft paraffin	to 100

Midge Bites.—Cod-liver oil provides complete protection. I use it in combination with quinine to make a "sunburn and midge cream." This is the formula:

Quinine acid hydrochloride	5
Cod-liver oil	20
Anhydrous wool fat	75
Oil of lavender or geranium	q.s.

DR. CLAUDE WILSON (Tunbridge Wells), president of the Alpine Club, writes on the prevention of sunburn as follows: Dr. McCann will find his question answered in the *British Medical Journal* for April 10th, 1926 (p. 681), in which there are some notes that would interest him. But, for practical purposes, there are many preparations sold by the chemists at most mountaineering centres. The original, and the best, is the pomade Sechehaye, made and sold in collapsible tubes, at 2.50 francs per tube, by the Pharmacie Hausser, 10, Bourg-de-Four, Geneva.

"J. F. W." has found an anti-insect preparation which is sold under the name of "No-Midge" to be very satisfactory. It is made by Adams, of 162, Higher Hillgate, Stockport, and is supplied in small collapsible tubes.

"YARRAMAN" thinks that "Perplexed" will find oil of citronella (a drop here and there on the dress, not forgetting the stockings) will keep away midges. The smell is pleasant. When camping out (he says) a cake of dry cowdung, lighted, will smoulder like touchwood, and keep away midges and mosquitos.

INCOME TAX.

Deductible Expenses.

"G. C." inquires what expenses can be deducted in computing assessable income from clinics, lectures, consulting practice, and journalism.

*** There can be no question about such expenses as professional postage and telephone costs, rent of consulting room, and professional subscriptions, which are clearly allowable. The cost of travelling from residence to consulting rooms is perhaps open to doubt. If professional work is done at home and the various earnings are so interconnected that they should be dealt with as a single entity—and there seems good ground for suggesting that that would be the correct course—we are of opinion that the travelling expenses are allowable.

Request to Produce Bank Pass Books.

"J. G." has for the past eight years employed a certified accountant to prepare his income tax returns. He has been asked to supply his bank pass books and details of his investments, sales, and purchases for some of the past years. Is this request supported by legal authority?

*** We presume that "J. G." has supplied certified copies of his professional accounts in the past; if so, the request seems quite unusual, and we suggest that "J. G." might ask the inspector of taxes to state the reason why it has been made to him. So far as the legal position is concerned, the inspector has no legal right to enforce the request, but the Commissioners responsible for the assessment in the last resort could require the production of the pass books, etc., if they decided to do so in the course of an appeal which "J. G." might make against an assessment made on his income.

Cash Receipts Basis.

"J. J." bought a share in a partnership at January, 1928. At the end of 1928 there was an amount of over £400 due to him for professional work, which, in many cases, was being paid off gradually in small weekly sums. The inspector of taxes has made an allowance for probable bad debts, but will not accept a computation of liability based on the cash receipts of 1928.

*** The inspector is legally correct. There is undoubtedly some hardship in having to pay tax on income before it is received, but as the law stands it is the amount of the earnings, whether received in cash or not, that determines the amount of the liability.

LETTERS, NOTES, ETC.

EMERGENCY OPERATIONS UNDER DIFFICULTIES.

DR. A. G. NEWELL (St. Leonards-on-Sea) writes: Dr. Moir's experience (*Journal*, June 7th, p. 1048) is interesting; it reminds me of one of several done under difficult conditions. I was travelling by train in Sylhet and we had arrived at a station. Immediately after the train started on its journey we heard an agonizing cry and loud shouts, and on looking out I found a native woman was lying on the rails. I shouted to the guard to stop the train. The woman had discovered this was the station she should have got out at; she had opened the door and evidently succeeded in getting to the lower step, from which she either jumped or fell. Her left foot was practically severed and hanging to the leg by a flap of skin; she had a large tear up the leg and the tibial and popliteal arteries were torn; there was much haemorrhage. I improvised a tourniquet, and took her into my compartment. I was to get out at the next station, where I had arranged for a trap to convey me to an estate about two and a half miles off. I had to put digital pressure on the femoral artery continuously till I reached my station. I then put a second improvised tourniquet and some firm bandaging on the femoral artery, and took the woman in my trap to the estate. There I arrived at dusk, and had to send ten miles for my instruments for amputation. In the early hours of the morning, in a small but dispensary, I amputated above the knee. I had as assistants an unqualified babu doctor and a native syce. There were three candles and a small oil lamp. After a few days the patient was fit enough to be conveyed to the railway hospital at headquarters. After ten or eleven days she died. The amputation was a success, but it was found that she had an enlarged spleen, which had burst from the fall and caused secondary internal haemorrhage.

HERPES AND VARICELLA.

DR. E. G. LEOPOLD GOFFE (Kingston-on-Thames) sends the following note: N. D., male, only child, aged 9 years, developed lobar pneumonia on October 15th, 1929. He was nursed at home by his mother, assisted by a grandmother and an aunt. N. D.'s mother, aged 46 years, developed herpes on November 1st, 1929. There was irritation of the skin, at the site of the subsequent eruption, for two days before the appearance of well-marked herpetic vesicles in the right groin and on the right labium majus, the upper and inner part of the right thigh, the inner side of the right knee, the right trochanter, the right buttock, and over the lumbo-sacral spine. None elsewhere. N. D., who occupied the same room as his mother, developed varicella on November 12th, 1929. He had well-marked vesicles on the face, scalp, palate, tongue, trunk, and limbs. The only visitors to N. D. and his mother during their illness were adults—namely, his father, grandmother, two aunts, and two uncles, none of whom showed any signs of herpes or of varicella. These contacts knew of no one who had either herpes or varicella before, during, or after N. D.'s and his mother's illness. This association between herpes and varicella I had noticed on several occasions while I was a resident in a fever hospital. A patient in a ward would develop herpes, and a fortnight later varicella would crop up in the ward, to be followed by successive outbreaks at regular fortnightly intervals.

RAPID LABOUR IN A PRIMIPARA.

DR. L. SCHAPERA (London, N.W.10) writes: I think the following case of rapid labour is worth recording. A primipara, aged 24, commenced labour at 8 p.m., and gave birth to a fully developed male child, weighing 6½ lb., at 11.55 p.m. I examined her at 10.55 p.m., when the os was only one fingerbreadth dilated; the membranes ruptured at 11.30 p.m.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 46, 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 283.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

552. Fatal Exophthalmic Goitre following Administration of Thyroid Gland.

E. MOLLER (*Acta Med. Scand.*, February 28th, 1930, p. 1) distinguishes hyperthyroidism from exophthalmic goitre; the latter presents some or all of the symptoms of hyperthyroidism, but in addition there is a soft goitre, characterized usually by thrill and bruit, exophthalmos, and the other well-known eye signs. Hyperthyroidism following thyroid administration is seen most frequently in obese patients, but it has occurred in cases of simple goitre, and in myxœdema after overdosage. The symptoms of exophthalmic goitre are usually aggravated by thyroid administration. Möller mentions eight previously recorded cases of exophthalmic goitre following thyroid medication; only one was fatal. Three patients suffered originally from myxœdema, and two from simple goitre. He reports a ninth case, the patient being a woman, aged 43, without a familial history of thyroid disease, who had had an artificial menopause induced on account of uterine fibromyomata two years earlier. Subsequently she became rather obese and thyroid tablets were prescribed; in six weeks she took between 110 and 120 tablets, and alarming dyspnœa, palpitation, insomnia, tremor, diarrhœa, hyperidrosis, thirst, and faintness developed. A moderately large goitre was present, accompanied by thrill and bruit; there was slight exophthalmos, a positive von Graefe's sign, and fine rapid tremor of fingers. For two weeks the condition remained unchanged. The basal metabolism at first showed an increase of + 52 per cent.; this fell to + 28 per cent. in four days. In spite of a high calorie diet, bromides, medinal, and iron, she became more restless, with occasional hallucinations and sphincteric incontinence, and died four weeks after admission to hospital. The etiology of exophthalmic goitre is still unknown. Möller adds that in this case the disease progressed for six months after cessation of thyroid medication; the preparation used was reliable and the dosage moderate. In view of the grave danger of the indiscriminate administration of thyroid extracts Möller considers that this treatment should be restricted to cases of evident hypothyroidism.

554. The Sciatic Syndrome.

A. VALERIO (*Rev. Sud-Americaine de Méd. et de Chir.*, April, 1930, p. 348) holds that sciatica is essentially a neuritis, and not a mere neuralgia; he refers to a previous publication on the subject by himself in which he insisted on the consideration of sciatica as a syndrome, and not a clinical entity; the work of the past five years has confirmed his opinion. Syphilis is a more common cause of sciatica than is commonly supposed; Valério has treated 30 cases, all successfully; in suspected cases, where the Wassermann reaction is negative in the blood and cerebro-spinal fluid, he attaches diagnostic importance to lymphocytosis and increase of albumin in the spinal fluid. The importance of looking for the Argyll Robertson pupil is also emphasized. In syphilitic sciatica the essential lesion is a funiculitis rather than a radiculitis, being usually localized to the region between the posterior root ganglion and the plexus. The treatment is by neosalvarsan in doses not exceeding 0.45 gram, up to a total of 4 grams in all, a second course being given after three months' rest, if necessary. Gleet and gonorrhœa are possible causes, and Valério has treated 22 cases of these conditions. In gleet the associated micro-organisms (including sometimes Koch's bacillus) are responsible; the treatment is by local diathermy for fifteen minutes daily, and ten to twenty applications are made, associated with the classical local genito-urinary treatment. Autohæmotherapy is sometimes employed, injections of 1, 1.5, 2, or 2.5 c.cm. being given at intervals of three or four days. In gonorrhœa the local genito-urinary treatment is supplemented by ultra-violet radiation in a series of ten treatments, beginning with one minute, and increasing by one minute daily; autogenous vaccines, although believed to act by colloidoclasic shock, have been found more effective than the stock kind. In eight instances the sciatica began during the first or second week after infection, being associated with an attack of rheumatism. In these cases, there is not only a neuritis, but also a peri-neuritis, and there is accompanying pyrexia; but also a peri-of a sacro-iliac arthritis should be looked for, and Valério has noted 16 such cases, which he designates "parasciatica." It should be noted that such gonorrhœal infections give rise to a true neuritis from bacterial and toxic action, and are not merely representative of reflex pain; the most usual lesion is probably a funiculitis, between the ganglion and plexus. Parasciatica is defined as sciatic pain caused by a lesion, not primarily of the sciatic nerve, which may affect the nerve roots before or after their exit from the bony canal, or the main nerve within the true pelvis; examples of exciting causes are lesions of the meninges or spinal column, pelvic tumours, adnexitis, and prostatic growths. Among less common causes Valério has seen four cases of appendicitis giving rise to sciatic pain, which ceased after appendicectomy; there was one case of popliteal lipoma, the size of the tumour being that of an orange. Sacralization of the lumbar spine must be considered as a possible cause of parasciatica, and 14 such cases were found in 92 radiographs of adults and children with sciatic and lumbar pain; in two cases sacralization was found unaccompanied by pain, and in some cases of spondylolisthesis and spina bifida occulta there is no complaint of pain.

555. Amelioration of Mental Disease after Influenza.

K. A. MENNINGER (*Journ. Amer. Med. Assoc.*, March 1st, 1930, p. 630) records 18 cases, of which several had come under his own observation, in which various psychoses had undergone improvement after an attack of influenza; 9 of the patients were males and 7 females, while in 2 the sex was not stated. In 7 the psychoses had lasted from twelve to eighteen months, in 3 for two to four years, in 6 from five to fifteen years, and in 2 the duration was not stated. Complete cure ensued in 11 cases; 3 patients showed some improvement, and 4 a remission of their mental symptoms. The diagnosis in the cases reported cured were mania (1 case), melancholia (2), schizophrenia (4), organic brain disease (1), epilepsy (2), and migraine (1). Menninger remarks that though it would be unsafe to draw any statistical conclusions from so small a series, both sexes, various syndromes, and illness of variable duration were included.

556. Aertrycke Infection.

P. M. HOLST (*Norsk Mag. f. Laegevid.*, February, 1930, p. 163) records an outbreak of enteritis in a farm where in the course of about six weeks between 20 and 90 pigs died of enteritis. About a fortnight after the beginning of the epizootic the seven inmates of the farm were also taken ill with diarrhœa, vomiting, fever, and headache. *B. aertrycke* was isolated from the stools of one of the patients, and was agglutinated both by the patients' serum and by serum from two sick pigs. It is probable, therefore, that both the epidemic and the epizootic were due to *B. aertrycke*.

Surgery.

557. Diathermy-Coagulation of Haemorrhoids.

DIATHERMY, according to G. FRIEDEL (*Paris Medical*, April 5th, 1930, p. 325), is the ideal treatment for haemorrhoids, in that the destructive action is strictly limited and the resulting scar is supple. Further, there is absolute safety, no infection nor haemorrhage, and conservation of the sphincter function. Contraindications are dilatations of the ano-rectal veins due to pressure (from a gravid uterus, fibroma, ovarian cyst, or other abdominal tumour), to cirrhosis of the liver, or to insufficiency of the right heart. The diathermy apparatus should supply at least 500 milliamperes of current. The active electrode is a needle mounted in ebonite; the other is a moist cubical pad, 15 cm. in each dimension. There should be ready to hand a 5 c.cm. syringe with two needles, each 5 cm. in length; iodized alcohol; a 1 in 10 solution of chromic acid; two pairs of Kocher's forceps; sterile compresses and cotton-wool; and an anal speculum. The anæsthetic recommended (for the operation is very painful) is butelline, a sulphate of para-amino-benzol-dibutyl-amino-propanol; to it adrenaline and potassium sulphate are added, and a preliminary injection of scopolamine morphine is recommended. The anal region having been swabbed with iodized alcohol, 4 to 5 c.cm. of butelline are injected at the four poles of the anus in the region of the subnucosa, a finger in the anus guiding the needle to avoid perforation of the mucosa. On each side of the sphincter zone 2 c.cm. more are injected deeply. Anæsthesia is generally complete in ten minutes. The sensitiveness of the mucosa having been carefully tested, the needle is introduced into the centre of

each pile, at a depth of 1 cm., and the current is passed until a white area around the needle indicates coagulation; the current is then switched off and the needle withdrawn. Haemorrhoidal masses would require four to six such punctures. Any superficial bleeding points are readily cauterized with the needle, and the scars are touched with chromic acid. Oedema may occur, of no consequence in internal haemorrhoids, while in external haemorrhoids hot and cold compresses cause rapid resorption. During the first twenty-four hours no food is given, but abundant fluid, with morphine at night, when it may be necessary to draw off the urine. If flatus is troublesome it may be evacuated through a well-lubricated gum-elastic catheter. On the third day light food is given and a further morphine injection. On the fourth and succeeding days a dose of castor oil is administered in paraffin to ensure loose motions. At the end of eight days the patient should be able to resume his normal life. Abscesses formed in three cases of the author's series of 300, and post-operative haemorrhage occurred in three other cases.

558. Pulmonary Abscess following Tonsillectomy.

P. H. PIERSON (*Arch. of Oto-Laryngol.*, March, 1930, p. 279) defines this condition as a consolidation of the lung followed by necrosis; it includes, therefore, many so-called "ether pneumonias." Two theories have been advanced to explain the development of these abscesses, the first being the more obvious aspiration theory, and the second the view that the lesion in the lung is caused by infected emboli from the site of operation; it is propable that both processes occur. More pulmonary abscesses follow operations under local than under general anaesthesia, a fact which constitutes strong evidence in favour of the embolic theory. Studying the bacteriology of the condition, Pierson found both aerobic and anaerobic organisms; he holds that the anaerobes are the agents in the formation of abscesses. The clinical picture is a sudden onset of cough, fever, and sweating, followed by foul sputum and loss of weight. The physical signs are few; dullness, the most constant of these, is usually accompanied by diminished breath sounds, and, later, signs of cavity formation will be found. Treatment calls for the co-operation of the physician, surgeon, and bronchoscopist. Medical measures result in cure in 50 per cent. of the cases, and the author emphasizes the value of postural drainage and prolonged rest in bed even when the prognosis is very favourable. Heliotherapy is of assistance as a general tonic. If postural drainage is unsatisfactory, bronchoscopy is performed, and granulation tissue is removed, thus opening up the drainage track. If after three months failure follows medical and bronchoscopic treatment, surgical intervention must be considered. As possible measures for the prevention of such abscesses the author suggests the careful pre-operative examination of the patient and attention to the condition of the mouth. During operation it is advisable to use suction apparatus, and to avoid the mass ligaturing of the tissues.

559. Cholecystitis.

A. C. NICKEL and E. S. JUDD (*Surg., Gynecol. and Obstet.*, April, 1930, p. 655) report a bacteriological and experimental study of 300 consecutive cases of the surgical resection of the gall-bladder at the Mayo Clinic; Rosenow's technique was used, with Wilkie's modification in some cases. Their results confirm a previous observation that viable bacteria are present in resected gall-bladders which have been the site of cholecystitis; the majority of those from patients with acute or subacute cholecystitis contained, in order of frequency, green-producing streptococci, Gram-negative bacilli, and staphylococci, while those from patients with chronic cholecystitis were sterile, as were also cultures from "strawberry" gall-bladders unless there was a complicating factor. The cultures were made irrespective of the reasons for removal, and of the amount of visible pathological change; 23 per cent. of the patients were men and 77 per cent. were women of whom 89 per cent. were married, many having a history of cholecystitis commencing or recurring soon after childbirth. Of the total number, 85 per cent. showed potential foci of infection in the teeth, tonsils, prostate, cervix, or sinuses. Cultures from cystic lymph nodes were approximately parallel with those from the walls of the gall-bladders. The streptococci from grossly diseased gall-bladders were of definite etiological significance, since they tended to reproduce cholecystitis and cholelithiasis in rabbits injected intravenously; staphylococci were found to be non-pathogenic when injected in pure culture. *B. coli* appeared to have a selective action for the gall-bladder, and were usually associated with the streptococcus in relatively acute cases and in those with stones in the common or cystic duct. The authors' conclusions agree with those of Branch, who regards "the disconcerting consistency of positive cultures from the acute cases" as "only equalled by the persistent lack of growth from the chronic cases."

Therapeutics.

560. The Salicylates in Acute Articular Rheumatism.

R. LUTEMBACHER (*Presse Méd.*, May 10th, 1930, p. 634) believes that rheumatic infection, like syphilis, should be treated for a prolonged period of one or two years, and preferably by intravenous injections. The dangers of using concentrated solutions of the salicylates are pointed out; these rapidly cause an induration of the venous walls and act also on the endocardium. Moreover, if the injection is not given very slowly, pains along the course of the nerves, and sometimes alarming malaise, are caused. Dilute solutions (1 in 20) are therefore recommended. Venous sclerosis has never been noted following the administration of such solutions, and better results have been obtained. Despite the tolerance of the organism for dilute injections of chemically pure sodium salicylate, Lutembacher has shown that there is a danger of overcharging the organism with sodium ions during prolonged treatment with this drug. This disturbance of the equilibrium is harmful for all the tissues, particularly the heart, and also impairs blood coagulability, a possibility which should not be overlooked in patients with more or less marked anaemia. A 1 in 20 solution of the salicylates of sodium, calcium, and potassium is advised; in this the ions are equilibrated in the physiological proportions of Ringer's liquid. The activity of this polysalicylate solution is said to be equal to that of the sodium salt alone; intravenous injections are remarkably well tolerated, the taste is less disagreeable, and oral doses are more acceptable to the stomach. Four cases, with the dosage employed in each, are described to illustrate the benefits resulting from this method. The doses should be reduced after the age of 30; young subjects, especially with grave forms of rheumatism which are complicated by subacute degeneration of the hepatic and renal parenchyma, singularly fail to respond to salicylate medication.

561. Digitalis as a Cause of Arrhythmia in Children.

S. P. SCHWARTZ (*Amer. Journ. Dis. Children*, March, 1930, p. 549) believes that digitalis may produce both the transient and the permanent forms of auricular fibrillation in children with heart disease. This possibility has in the past been questioned on the ground that other factors which might have been responsible for the arrhythmia had not been eliminated. An account is given of two patients, aged 6½ and 12 years respectively, in whom the onset of fibrillation seemed to be definitely attributable to digitalis administration. The first child received daily 3 c.cm. of the tincture of digitalis as treatment for severe heart failure, accompanied by oedema of the legs and ascites, in the course of an attack of rheumatic fever. After five days definite improvement resulted, and the dosage was continued despite progressive prolongation of the PR interval in the electro-cardiogram. On the eighth day dropped beats were observed, auricular fibrillation developed, and death followed. The second child suffered from organic valvular heart disease and recurrent bouts of rheumatic fever. Cardiac insufficiency with oedema appeared during one of the exacerbations, and large doses of tincture of digitalis were given. After 32 c.cm. had been administered over nine days auricular fibrillation developed, with a slow rhythm and persistent coupling. Six days later the normal rhythm was restored. That auricular fibrillation is an early disturbance of the cardiac mechanism produced in children by digitalis is suggested by the appearance of this arrhythmia before the onset of premature ventricular beats. Additional reasons are given for believing that the development of fibrillation is the result of vagal stimulation by the drug during a period of active carditis. The author concludes that the administration of digitalis is contraindicated in children with rheumatic fever and signs of cardiac insufficiency.

562. Serum Therapy in Gas Gangrene.

E. E. LARSON and D. S. PULFORD (*Journ. Amer. Med. Assoc.*, March 1st, 1930, p. 613) repeat the warning that infection by anaerobic bacteria is not uncommon in civil practice. It may be suspected in lacerated wounds and compound fractures, especially where earth or woollen material has entered the lesion, and if the patient has, usually within the first twelve hours, pain disproportionate to the degree of injury; high temperature and pulse rate, with flushed face and unimpaired mental function; swelling of the injured part, with pallor of the surrounding skin; and a dirty creamy tint of the wound margins with blood-stained serum but no pus on the dressings. Later, bubbles of gas can be expressed, and crepitation is felt under the skin. Smears of the secretion and cultures should be made immediately, some of the macerated tissue being placed in a test tube and covered with melted agar. Bubbles appear after a few hours' incubation if anaerobes are present. An *x*-ray examination

may show bubbles in the tissues before crepitation can be felt. Treatment must be applied early and thoroughly. It consists in the removal of all devitalized tissue and foreign matter, leaving the wound open; frequent (three-hourly) irrigation, preferably with 1 per cent. chloramine, and immersion of the injured part in this solution for an hour three or four times daily; and the administration for an hour antiserum—*B. perfringens* (*welchii*), *Vibrion septique*, and *B. oedematiens*—both intravenously and locally into the deep and superficial tissues above the wound. The dose of the serum is as much as 50 c.cm. in 100 c.cm. of physiological saline solution for daily intravenous injections, and 50 c.cm. for local application. Seven cases are recorded by the authors, in all of which the anaerobic infection was successfully controlled. In one instance amputation was performed eleven days after the injury, but the patient died from streptococcal septicaemia a week later. The stump was free from anaerobic infection. The other patients recovered.

563. **Treatment of Meningococcal Septicaemia.**

J. PUJET (*Thèse de Paris*, 1930, No. 476) records seven cases in patients aged from 16 to 53, of meningococcal septicaemia characterized by intermittent fever, an erythematous eruption on the limbs, myalgia, and good general condition. With one exception, none showed any signs of meningitis. In the first case, after all other methods had failed, recovery took place after two intravenous injections of trypaflavine. In the second case proteinotherapy was of no benefit, but recovery followed the injection of trypaflavine. In the third case cerebro-spinal meningitis, which was followed by meningococcal septicaemia on which the disease had no action, but a cure was effected by injections of yellow. In the fourth and fifth cases, in which the disease had proved refractory to serum and vaccine treatment, were cured by two injections of trypaflavine. In the sixth case, when trypaflavine was given on the twentieth day, only a slight and transient improvement resulted from a single dose of 0.10 c.cm., but a cure was obtained by daily repetition of the dose. In the seventh case, where some reduction of the pyrexia had been obtained by pyoformine, four injections of trypaflavine produced a cure.

Radiology.

534. **Combined Radium and X-ray Therapy in Rectal Carcinoma.**

RECTAL cancers are notoriously difficult to cure because 40 to 50 per cent. are inoperable when first seen; the rectum is in daily use; the tumour mass is not easily accessible; the degree of dissemination cannot be estimated by physical examination; and the complete removal of all cancer-bearing tissue is difficult and accompanied by a high immediate mortality. I. ARONS (*Radiology*, March, 1930, p. 232) believes that radium and *x*-ray treatments are palliative measures which relieve suffering and prolong life. Epithelioma or squamous-cell carcinoma of the anus is uncommon (only 3 to 4 per cent. of all rectal cancers), and its most satisfactory treatment is irradiation by the interstitial deposition of small metal-filtered radon implants, known as gold or platinum seeds. The remaining cancers of this region are adenocarcinomas, of which the four common types are adenocarcinoma, papillary carcinoma, the colloid or gelatinous carcinoma, and the destrnens, the colloid or malignant adenoma or adenoma sclrrhus or fibrocarcinoma. The colloid and scirrhus, especially the latter, are radio-resistant. Rankin and Broders have divided these growths into four groups or grades, based on their degree of malignancy. A knowledge of the lymphatic drainage of the rectum is essential in order to place properly interstitial foci of radon, and thus anticipate and prevent the dissemination of the cancer. The lymphatics of the rectum are: the intramural lymphatics, which are arranged in two plexuses, the submucous and the intermuscular; the intermediary lymphatics, which spread in three directions—extramural lymphatics, which spread superiorly, laterally, and inferiorly. Ano-rectal cancer is disseminated by direct extension or continuity, by permeation of the lymphatics, and by metastases through the blood vascular system. The lymph spread may follow any of the lymphatic pathways mentioned above, and the proper arrangement of radio-active foci is as follows: gold or platinum radon seeds superficially in the submucosa of the rectum in the same segment in which the cancer occurs, in order to prevent the circular spread by the submucous plexus; similar seeds in the wall above and below the cancer, to prevent the longitudinal spread by the intermuscular plexus; similar seeds of similar seeds or radium element needles in the perianal ...ion, the externa... fossa, the treatments to be supplementary to the direct attack on the tumour mass. Before the cancer is irradiated colostomy should be performed, and, within a few days of this, irrigation of the lower loop with 5 per cent. sodium bicarbonate should be begun for cleansing purposes. In the absence of faeces and with continual irrigation the infection subsides and the tumour seems to become smaller. Two weeks after the colostomy is made, a pelvic cycle of *x*-irradiation is given, followed almost immediately by interstitial radium therapy. The technique employed is fully described. Either sacral or spinal or nitrous oxide anaesthesia is sufficient for the introduction of the needles or seeds.

565. **X-ray Treatment of Syringomyelia.**

RAYMOND, OBERTHUR, and DELHERM were the first (in 1905) to report the improvement, from both a motor and sensory standpoint, in a case of syringomyelia following spinal *x*-ray treatment for a year. DELHERM, MOREL-KAHN, and DESGREZ (*Presse Méd.*, February 26th, 1930, p. 281) summarize the results reported by various authorities, and record those obtained in 15 personal cases by this method. Of the latter, 9 (60 per cent.) were improved, 1 remained stationary, and 5 (33 per cent.) became aggravated. Of 153 cases collected from the literature, 124 (73 per cent.) were improved, while the others either remained stationary or became worse. Syringomyelia advances by successive recrudescences, interspersed with remissions which are sometimes prolonged, and the lesion is apt to extend both above and below. thus necessitating an irradiation greatly beyond the limits of the suspected region. In this disease the cord resembles a soft sac, which collapses after its liberation; the hollowed cavity in the middle of the cord, which histologically characterizes a glioma, sends prolongations, sometimes very extensive, to the upper and lower segments. Thus both compression and destruction of tissue occur. In the latter case there can be no hope of any useful repair of the tissues; on the other hand, it is conceivable that, if the compression is arrested, the nervous elements, freed by the action of the irradiation, may resume their activity. Many authorities believe that syringomyelia is due to the formation of a glioma; it has been shown that *x* rays have a considerable action on gliomatous tissue composed of young cells, and that fibrous tissue is radio-resistant. Bergonié-Tribondeau has asserted that radiotherapy can be efficacious in lesions composed of young cells but not in fibrous ones; that in every case it can cause the arrest of the disease and even a partial regression; but that, as destroyed tissue can never be re-formed, there is no question of complete cure. The present authors believe that radiotherapy can bring about an improvement, sometimes marked, in an appreciable number of cases, provided that it is begun early in young subjects and continued for a long period, and that its applicat on is extended considerably beyond the clinical seat of the lesions. Even in cases of long duration this treatment is recommended as being the only method capable of producing any improvement. Small doses at short intervals are preferable to large ones at long intervals. The dosage is 400 R, and two exposures are given weekly, each side of the cord being alternately irradiated. At the commencement, intervals of three or four weeks are allowed between each series, but as improvement becomes more marked and permanent these intervals are lengthened. The skin should be carefully watched because of the importance of protecting possible sites for future irradiations.

535. **The Electrical Treatment of Arthritis.**

W. B. SNOW (*Med. Journ. and Record*, November 20th, 1929, p. 559) stresses the importance of dissipating the infiltration, or local swelling, or stasis in the joint structures in all cases of arthritis. An experience of thirty years has convinced him that electricity may be properly employed in acute joint conditions. He uses the static current in the forms of static wave current, static sparks, and static brush discharge as his method of treatment. The static current acts directly on the cell mass, overcoming the resistance of the skin, which the constant current of low voltage cannot do. It thus sets up among these cells active impulses of contraction which expel the accumulated elements from the lymph spaces and so effect a complete drainage of the local field where stasis is present. Thus the aim of treatment is achieved—diminution of pain and restoration of movement. Snow employs this treatment for cases of traumatic arthritis, and cites cases to show the rapidity with which movement is restored. In toxic arthritis the etiological factor should be thoroughly investigated for diagnosis, and methods directed to the removal of causative features. In this connexion Snow mentions that he has found diathermy of the septic focus very beneficial. Rheumatoid arthritis, even in apparently hopeless cases, has responded to static electricity. Children suffering from Still's disease have also gained quick relief; static current and replacement.

Obstetrics and Gynaecology.

567. Acute Sacculation of the Uterus.

W. FLETCHER SHAW (*Journ. Obstet. and Gynaecol. of the British Empire*, Spring, 1930, p. 72) records the case of an unmarried nulliparous woman, aged 31, who suffered from acute abdominal pain after three months' amenorrhoea; she was found to have an extremely tender cystic swelling, surmounting and of equal size with a uterus enlarged to the size of three months' pregnancy. The pulse rate and temperature were normal. The pre-operative diagnosis was pregnancy with red degeneration of a subperitoneal fibroid. Laparotomy showed a median thin-walled spherical cystic swelling the size of a cricket ball springing from the upper edge of the uterus, unconnected with the adnexa; when it was incised the swelling gave vent to liquor amnii and a four months' foetus. The tumour communicated by an aperture admitting two fingers with a uterus the walls of which were of normal thickness. The placenta was inserted in the uterine cavity, and both that and the tumour cavity were lined by the foetal membranes. The incision in the sacculation was stitched. At a second operation two years later the uterus was found to be normal save for a thin-walled median vertical depression extending from the fundus down both the anterior and posterior walls. Shaw describes three cases, and illustrates two similar cases from the literature. He ascribes the sacculation in his case to a weakness in the uterine wall at the site of fusion of the Müllerian ducts, and the abdominal pain to forcible distension by the growing ovum of a non-resistant portion of the uterus at the apex of the abnormal zone.

568. Sodium Iso-amylethyl Barbiturate in the Late Toxaemias of Pregnancy.

J. H. MOORE (*Amer. Journ. Obstet. and Gynecol.*, April, 1930, p. 544) reports four cases of grave toxaemia occurring late in pregnancy, in which sodium amytal (sodium iso-amylethyl barbiturate) played an important part in treatment. Three of the patients were suffering from nephritis which was complicated by pregnancy. Fear of approaching labour added a serious mental hazard to these patients, who in any case could only be considered poor obstetrical risks. The fourth was the only case which showed all the symptoms and signs of eclampsia. The problem of anaesthesia as well as analgesia was greatly simplified by the use of sodium amytal. No ill effects were noted in the four premature infants of these toxic mothers, but two of the mothers showed symptoms of moderate shock, one six hours and the other ten minutes after the injection of the drug. The depression in both cases was only temporary; it occurred in patients who had been unusually nervous and apprehensive before the induction of labour. The prompt anaesthetic and sustained analgesic effect in all the patients was satisfactory.

569. Pregnancy and Eruptive Fevers.

H. DUFOUR (*Journ. de Méd. de Paris*, April 3rd, 1930, p. 287) states that erysipelas does not usually have an unfavourable influence on pregnancy; Roger, Legendre, and himself had recorded 17 cases of erysipelas in which delivery was normal. Contrary to what might have been expected, streptococcal infection in the puerperium in such cases is rare. Of 20 pregnant women who contracted measles under Dufour's observation, 9 either aborted or had a premature confinement; while of 10 pregnant women who contracted scarlet fever, none aborted, and only one had a premature confinement at the eighth month. As regards lactation, the mother may be allowed to suckle her child provided that care is taken to prevent infection of its umbilicus, since no condition is more serious than erysipelas in the newborn. In the absence of broncho-pneumonia, which is very contagious, a woman suffering from measles should be allowed to suckle her child, and it is generally agreed that lactation may be continued by a mother who is suffering from scarlet fever.

570. Treatment of Uterine Bleeding.

G. DANEFF (*Zentralbl. f. Gynäk.*, March 29th, 1930, p. 808), from an experience of 72 cases of menorrhagia and/or metrorrhagia, 42 of which were ascribed to altered ovarian function, and in 30 of which no organic disease could be detected in the pelvis or elsewhere (patients of this group were of the delicate, slightly cyanotic, and asthenic type), recommends the administration of digitalis, preferably intravenously as digalen. He reports the disappearance of morbid uterine bleeding after this treatment, even in patients in whom objective cardiopathic signs were absent or indefinite. The treatment is also of considerable use, it is said, in cases in which morbid bleeding coexists with inflammatory adnexal disease.

Pathology.

571. Bacillus typhosus Type G.

L. K. WITKOROW and G. I. SINAI (*Deut. Arch. f. klin. Med.*, January, 1930, p. 60) state that in a previous paper Witkorow bestowed the name of "Type G" on a special bacillus which serologically was closely related to Gaertner's bacillus, and in its biochemical features occupied a position midway between the typical typhoid organism (Type T) and paratyphoid bacilli. The present paper deals with the etiological role of "Type G" in diseases of a typhoid character. From examination by the Widal and Castellani tests of 302 serums from patients with clinical symptoms of enteric fever the following results were obtained. (1) 12 per cent. of the patients were infected with "Type G"; in 8 per cent. of these cases this infection could be determined by the Widal test alone, and in 4 per cent. by the Castellani test. (2) In a certain number of cases "Type G" infection was determined by growth of typical cultures from the blood and stools. (3) The serological specificity of "Type G," which had been formerly demonstrated by examination of the serums of artificially immunized animals, was confirmed by the clinical results obtained with Castellani's test, and in like manner Witkorow's previous conclusions were confirmed as regards the character of the serological relations between "Type G," *B. paratyphosus* N_2 (Russian terminology), and *B. enteritidis* Gaertner. Clinical observation of patients suffering from "Type G" infection yielded the following results. (1) Infection with "Type G" may produce two kinds of diseases—namely, in 77 per cent. the symptom-complex of typical enteric fever, and in 23 per cent. a condition in which symptoms of gastro-enteritis predominated. (2) "Type G" must be ranked with *B. typhosus* and *B. paratyphosus* A and B as a cause of enteric fever. (3) Infection with "Type G" probably explains some of the cases of clinical enteric fever in which the Widal test for typhoid or paratyphoid infection is negative. Investigation of a family epidemic of "Type G" infection in which seven persons were involved showed that the epidemiology of "Type G" infection in its dissemination in the form of isolated foci, and in the importance of carriers and articles of food, closely resembled that of typical enteric fever.

572. Passage of Inert Materials through the Intestine.

F. HOELZEL (*Amer. Journ. of Physiol.*, March, 1930, p. 466) has studied the rate of passage of various inert materials through the digestive tracts of various animals and man, the substances used being rubber, cotton knots, seeds, glass beads, aluminium, steel, silver, and gold. The rates of passage were found to be more or less proportionate to the specific gravity of the materials, the heavier ones passing more slowly than the light. The rates varied considerably in different species and individuals. In rabbits stasis occurred more rapidly in the duodenum, and to a lesser extent in the stomach, colon, appendix, and caecum. In guinea-pigs most of the heavy material was retained in the stomach and less in the caecum; in rats the caecum was the main site of stasis, and in pigeons and hens the gizzard. In man heavy materials tended to accumulate mainly in the terminal parts of the ileum, the colon, and the caecum. The stasis of gold was so great that intestinal obstruction could be produced with it in rabbits, but not in guinea-pigs, rats, or mice. A relation was traced between the gastro-intestinal motor activity of female rats and their fertility, the viability of their young, and the sex ratio in their litters.

573. Filterable Elements of the Tubercle Bacillus.

J. VALTIS (*La Vie Méd.*, March 10th, 1930, p. 245) discusses the acid-fast bacilli found in the glands of guinea-pigs most easily during the first fortnight of infection and also during the first two months following the inoculation of certain filterable elements of tubercle bacilli and tuberculous material. He gives reasons for believing that these bacilli were not previously present in the animals before inoculation, nor are they "paratubercle" bacilli; and he maintains that they have an attenuated virulence which can be recovered after passage through several animals. The possibility of imperfect technique is discounted, new Chamberland L2 candles having been used, and the experiments being [illegible] controlled by a twenty-four-hour-old culture of [illegible] cholera. With Professor Calmette, the author chicken cu[illegible] probability that the so-called granulations of suggests the [illegible]own into smaller invisible elements capable Much break[illegible]searches of Kahn and Torrey seem to favour of passing [illegible]als.

METATARSALGIA

The intense discomfort and nervous strain caused by a partial or complete collapse of the arch of the foot brings this condition to the notice of the physician.

The invention of the Korcet Shoe has made it possible to deal with each stage of the complaint adequately. This shoe is unique and contains built-in elements in its construction which give complete support, a resilient spring, lateral supports, and a metatarsal pad on which the ball of the foot rests in comfort.

Note.

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

VARICOSE VEINS IN HOT WEATHER.

Wearers of Elastic Hosiery find the ordinary type of Stockings, etc., rather trying during a hot spell.

We now have all grades made in a special weave, which, whilst still retaining all the supporting qualities, by its perforated finish, allows free passage of air to the limb.

These appliances are thereby lighter in weight, cooler in wear, and a great comfort to patients in the Summer Season.

The cost is only fractionally more (owing to the increase in weaving), but it is economy in the truest sense, because the Winter Hose can be returned for necessary cleaning and repairing.

Excessive perspiration, which so quickly shortens the life of elastic goods, is avoided by the use of

SALT'S OPEN-WEAVE ELASTIC HOSIERY.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It corrects sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

FREE HOME TESTS arranged for Doctors and Patients. Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special department for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The grade house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the E-tate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payments. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Apply the DEAN, Educational Committee.

County Borough of Birkenhead.

MEDICAL OFFICER'S DEPARTMENT.

ASSISTANT MEDICAL OFFICER OF HEALTH AND BACTERIOLOGIST.

Applications are invited for the above appointment from duly qualified men holding a Diploma in Public Health or a qualification in State Medicine.

The salary will be at the rate of £750 per annum, rising by annual increments of £50 to £900 per annum.

The successful candidate will be engaged on bacteriological and biochemical investigations in connection with the work of the Corporation's Hospitals, etc. He will also be required to undertake any other medical duties which may be assigned to him by the Medical Officer of Health, under whose supervision and direction all his work will be carried out.

Candidates must produce satisfactory evidence of special post-graduate training and practical experience in bacteriological and biochemical work.

Canvassing in any form whatever, direct or indirect, will disqualify an applicant. This condition will be strictly enforced.

Particulars of the appointment and form of application may be obtained from D. MORLEY MATTHESON, Esq., M.A., M.D., Medical Officer of Health, 9, Hamilton Square, Birkenhead.

Applications must be received not later than Monday, June 30th.

E. W. TAME, Town Clerk.

Town Hall, Birkenhead.

June 6th, 1930.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

The Surrey County Council invites applications from registered male Medical Practitioners for the post of Assistant Medical Officer. Applicants must not be over 35 years of age, and must possess the Diploma of Public Health. The duties of the post include the Medical Inspection of School Children; work under the Maternity and Child Welfare Regulations; and Acts, and Venereal Diseases Regulations; and such other Public Health duties as may be allocated to him. The person appointed will be required to devote his whole time to the service of the County Council and reside in the County. The salary will be £600 a year, rising by annual increments of £20 to a maximum of £700, together with travelling expenses in accordance with the Council's scale.

The person appointed will be required to pass a medical examination and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form which can be obtained together with further particulars from the County Medical Officer, County Hall, Kingston-upon-Thames, to whom the completed forms should be returned not later than Saturday, June 28th. All communications must be endorsed "Assistant Medical Officer."

Any form of canvassing is strictly forbidden, and will disqualify.

EGYPTIAN UNIVERSITY.

FACULTY OF MEDICINE.

Applications are invited for the newly created CHAIR OF PROFESSOR OF HYGIENE. Applicants must have a University Medical qualification and at least ten years' experience of Public Health work, preferably in a Tropical country. Candidates must have a recognized qualification in Public Health and preferably a qualification in Tropical Medicine and Hygiene. They must have held a post in a recognized institute.

The duties of the Professor include giving a Course of Instruction to Under-Graduates and a Post-Graduate Course for the Diploma of Public Health and Tropical Medicine. He will also conduct Research work. The language of instruction is English.

The salary offered is £E1,500 (approximately £1,538) a year, and the appointment will be on contract for three years' renewable. The contract may be terminated by either side by three months' notice in writing.

One month's salary will be paid in lieu of travelling expenses if the successful applicant is resident in Europe.

If an official of the Egyptian Government is selected for the post he will not receive the advertised salary unless it is sanctioned by the Financial Authorities.

Applications, with copies of published Research and copies of testimonials, should be addressed to the Dean of the Faculty of Medicine, Egyptian University, Cairo, so as to be received by him not later than September 20th, 1930.

Further details may be secured by application to the DEAN.

Egyptian Government.

EGYPTIAN UNIVERSITY.

FACULTY OF MEDICINE, DENTAL SCHOOL.

Applications are invited for the post of LECTURER IN DENTAL SURGERY and ASSISTANT DENTAL SURGEON in the DENTAL SCHOOL, CAIRO. The duties will be instructional and clinical.

Preference will be given to candidates possessing the L.D.S.R.C.S.England.

The appointment will be on contract for three years at a salary of £E.420 (approximately £492) a year, and private practice is allowed.

One month's salary will be paid in lieu of travelling expenses if the successful applicant is resident in Europe.

Applications, with details of experience and copies of recent testimonials, should be addressed to the Dean of the Faculty of Medicine, Kasr-el-Aini, Cairo, so as to reach him not later than September 20th, 1930.

County Borough of St. Helens.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the post of Assistant Medical Officer of Health (male).

The duties will be mainly in connection with Maternity and Child Welfare and the School Medical Service, but will frequently include Tuberculosis, Infectious Disease, and General Sanitary work, so that the post gives considerable general experience.

Candidates must have had special experience in the diseases of children and infants, and possession of a Diploma in Public Health is very desirable.

Salary £600 per annum, subject to a five per cent deduction for purposes of the Council's Superannuation Scheme under the Local Government and other Officers Superannuation Act, 1922.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, St. Helens, and completed applications, accompanied by copies of not more than three recent testimonials, should reach him not later than Monday, June 30th.

FRANK HALEWELL, Medical Officer of Health.

Town Hall, St. Helens.

June 7th, 1930.

Staffordshire County Council.

COUNTY BACTERIOLOGICAL LABORATORY.

A BACTERIOLOGIST is wanted for the above Laboratory, Stafford.

The person appointed must be a registered Medical Practitioner and must have had experience in the routine of a Public Health Laboratory, including the Wassermann Reaction.

Remuneration at the rate of £250 per annum, with a fee per week and necessary travelling expenses.

Applications should be addressed to the undersigned.

EUSTACE JOY, Clerk of the County Council.

County Offices, Stafford.

June 16th, 1930.

EAST AFRICAN MEDICAL SERVICE.

VACANCIES at present exist for MEDICAL OFFICERS in the EAST AFRICAN MEDICAL SERVICE.

Qualifications.—Candidates must be British subjects of European parentage and under 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

Salary.—£600 per annum, rising by annual increments of £30 to £840 per annum, and thence, subject to an efficiency bar, by £40 to £920 per annum.

Quarters.—Free quarters are provided or an allowance is given in lieu.

Passages.—Free first-class passages are provided both on first appointment and when proceeding on or returning from leave. A married officer will be granted an allowance towards the cost of his family's passage once each way in respect of each tour of service.

Terms of Appointment.—The appointments are pensionable subject to a probationary period of two years in the first instance.

Length of Tour of Service.—The normal tour of service is 20 to 30 months, after which leave is granted, with full salary, for 2½ to 3½ days, according to the districts in which the officer has served, for each month of service, plus the period of the voyage to England. If the officer is returning to East Africa for further service, he receives a further similar amount of leave, plus the period of the voyage to East Africa.

Course of Instruction in Tropical Medicine.—Selected candidates will normally be required to undergo a course of instruction in Tropical Medicine and Hygiene before proceeding overseas.

Duties.—Though Medical Officers are appointed in the first instance for general service, there are good opportunities for work in special branches of medicine and surgery and for research.

Further particulars and forms of application may be obtained on application, in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Countess of Dufferin's Fund.

WOMEN'S MEDICAL SERVICE FOR INDIA.

Medical Women are invited to apply for the following posts, which must be taken up by the end of October:

(1) MEDICAL WOMAN for General Service. Emoluments: Rs. 550 per mensem, rising; furnished quarters; provident fund; passage and outfit allowance.

(2) MEDICAL WOMAN, with special experience in Maternity and Child Welfare and administration in Public Health work. Emoluments: Rs. 750 per mensem, rising; furnished quarters; provident fund; passage and outfit allowance.

Applications, on special form to be obtained from undersigned, with copies of three recent testimonials, should be returned by Friday, July 11th, to Hon. Secretary, United Kingdom Branch Dufferin Fund, c/o Major-General Sir LEONARD ROGERS, India Office, Whitehall, S.W.1.

June 10th, 1930.

City of Birmingham.

FIRST ASSISTANT MEDICAL OFFICER required. Salary £600 per annum, together with board, etc. Adequate resident experience in a large Infectious Diseases Hospital is essential. Applicants should preferably also have held a resident post in a Children's Hospital, and should possess a post-graduate qualification in Medicine or Public Health. Forms of application may be obtained from Dr. E. H. R. HARRIES, Medical Superintendent, City Hospital, Little Bromwich, Birmingham, and should be returned to him on or before Thursday, June 26th.

P. H. C. WILTSHIRE,
Town Clerk.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM (333 Beds).

APPOINTMENT OF ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Assistant Medical Officer, to take up duties on August 16th.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Preference will be given to applicants with previous Hospital experience; some experience of Bacteriology is desirable.

Salary £350 per annum, with board, residence, and laundry in addition.

The appointment is made in the first instance for a period of twelve months, renewable at the expiration of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Medical Officer, Baguley Sanatorium," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must reach him not later than Saturday, July 12th.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of the office, to contribute to the Corporation Superannuation Fund, and to execute the deed of service. Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
Town Hall, F. E. WARBRECK HOWELL,
Manchester. Town Clerk.
June 5th, 1930.

Applications, with copies of four recent testimonials, to be forwarded to Mr. REGINALD S. MILFORD (Hon. Sec., Manchester Ear Hospital), c/o Mr. W. J. ELLAM, 33, Brazennose Street, Manchester.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay	Year of Total Service.
1	2	3	4	5
Lieut.		Rs.	Rs.	1st
			150	2nd
			150	3rd
		560	150	4th
			150	5th
			£15	6th
Capt.	(i) During first 3 years' service as Captain	650	£15	7th
			£25	8th
			£25	9th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	10th
			£25	11th
			£25	12th
	(iii) With more than 6 years' service as Captain	850	£20	
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 9 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250	£20	13th and over
Lieut.-Col.	(i) Until completion of 23 years' total service	1500		
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	£00

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1 The Selection Committee will meet at the India Office in July, and the selected candidates will be required to join a course of instruction commencing early in August, 1930. Applications should be submitted as soon as possible.

Dumfries and Galloway Joint SANATORIUM.

RESIDENT MEDICAL SUPERINTENDENT.

The Dumfries and Galloway Joint Sanatorium Board invite applications for the appointment of Resident Medical Superintendent of (1) the Board's Sanatorium, and (2) an Infectious Diseases Hospital, which adjoin and are situated at Lochnaben, Dumfriesshire. The officer will be required to devote his whole time to the duties and not to engage in private practice. Salary £700, rising by annual increments of £50 to £800 per annum, with free house, coal, light, and laundry. Candidates must be regularly qualified in medicine and surgery.

Full particulars and forms of application may be obtained from the undersigned, with whom applications (on the prescribed form) must be lodged prior to Tuesday, June 24th.

County Buildings, Dumfries. JOHN ROBSON, Clerk of the Board.

A. STANLEY BRUNT,
June 2nd, 1930. Gen. Supt. & Sec.

Appointment of a Registered Medical Man or Woman as a Clinical Research Worker in Mental Deficiency.

The MEDICAL RESEARCH COUNCIL, the governing body of THE DARWIN TRUST, and the COMMITTEE OF THE ROYAL EASTERN COUNTIES INSTITUTION for the MENTALLY DEFECTIVE at COLCHESTER, invite applications from registered Medical Men or Women to undertake research work in Mental Deficiency.

The person appointed will be a member of the Medical Staff of the Royal Eastern Counties Institution and will be expected to take some part in the Administrative and Clinical work of the Institution itself, but the major part of his work will be an investigation into the causes of mental deficiency from the clinical, social and genetic aspects. A Social Investigator will be appointed to assist in the work.

Commencing salary at the rate of £600 a year, non resident.

A form of application can be obtained from Mrs. DARWIN, The Orchard, Huntingdon Road, Cambridge, which must be completed and returned to her before July 14th. Duties to commence October 1st, 1930.

Erith Urban District Council.

OPHTHALMIC SURGEON.

Applications are invited from duly qualified and Registered Medical Practitioners who have had special experience in Refraction work and are Education Authority, for the above appointment under the Erith Education Committee.

Sessions are usually held fortnightly on Fridays, afternoons at the School Clinic.

The fee payable is £2 12s. 6d. per session, but shall not exceed two hours in duration.

Further information is desired it may be obtained from Dr C. HERINGTON, Council Offices, Erith, to whom applications and copies of not more than three recent testimonials must be sent, to reach him not later than July 1st.

Council offices, DOUGLAS S. TWIGG.
Clerk to the Council.

Erith.
June 13th, 1930.

Borough of Ilford.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation invites applications from legally qualified Medical persons of both sexes for the office of Assistant Medical Officer of Health, for duties in connection with Maternity and Child Welfare work, School Medical Inspection, and General Public Health work. Candidates for the appointment must have had special experience in Midwifery since qualification, and, subject to this, preference will be given to candidates who possess the Diploma of Public Health or similar qualification, and have had experience in Children's Diseases.

The commencing salary of the officer will be £600 per annum (no bonus), rising by one annual increment of £25 to £700 per annum, subject to satisfactory service.

The Person appointed will be required to devote whole time to the duties of the office, to reside within easy distance of the Corporation's Maternity Home, and to enter into an agreement for the due performance and fulfilment of all the duties and conditions governing the appointment. The appointment will be subject to a satisfactory medical examination and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials, and by copies (which will not be returned), endorsed "Assistant Medical Officer of Health," must be received at my office, at the Town Hall, Ilford, not later than Tuesday, July 1st.

Canvassing Members of the Council, directly or indirectly, is prohibited and will disqualify.

By Order,
ADAM PARTINGTON,
Town Clerk.

Town Hall,
Ilford.
June 17th, 1930.

City of Liverpool.

PUBLIC ASSISTANCE COMMITTEE.

RESIDENT ASSISTANT MEDICAL OFFICER (Male).

The Committee invite applications for the appointment of a Resident Assistant Medical Officer (male) at the MILL ROAD INFIRMARY, LIVERPOOL, for a period of one year, at a salary after the rate of £200 per annum, together with the usual residential allowances.

Candidates must be single, fully qualified, and registered.

Applications, stating age, qualifications, etc., with copies of three testimonials, to be received by the undersigned not later than 10 a.m. on Thursday, June 26th.

WALTER MOON,
Town Clerk.

Public Assistance Office,
Bangham Terrace, Liverpool.
June 17th, 1930.

City and County of Newcastle-upon-Tyne Education Committee.

Applications are invited for an appointment as full-time ASSISTANT SCHOOL MEDICAL OFFICER (man or woman). Salary £500 per annum, rising by £25 per annum to a maximum of £700 per annum in accordance with the National scale. Applicants should have had at least three years' experience in the practice of their profession subsequent to obtaining their qualifications.

Form of application and particulars of the appointment may be obtained by sending a stamped addressed foolscap envelope to the Director of Education, Education Office, Northumberland Road, Newcastle-upon-Tyne.

Applications will be received up to and including June 28th.

North Shields and Tynemouth Dispensary

Applications are invited from qualified Medical Practitioners for the post of MEDICAL OFFICER to the North Shields and Tynemouth Dispensary. Salary £400 per annum, non-resident. Applications, stating age, qualifications, and experience, with copies of not more than three testimonials, to be sent to the Hon. Secretary, North Shields and Tynemouth Dispensary, 20, Church street, North Shields, not later than June 25th.

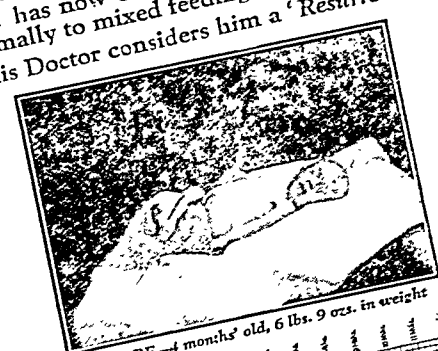
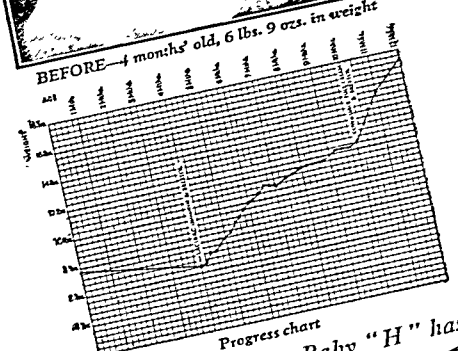
NATURALLY RICH

IN VITAMIN "D"



A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs 9 ozs.) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia. The infant was put on to LACIDAC (Separated) with a small quantity of BRESTOL and immediately made steady progress.



At 6 months he had gained 3 lbs. 7 ozs. and by the end of another 4 months his weight was 12 lbs. 6 ozs., and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol.

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby.

His Doctor considers him a 'Resurrection.'

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight

Progress chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight

June, 1930. Baby "H" has now won a prize in a Baby Show!

Write for literature and clinical samples of Lacidac and Brestol.

ISSUED WEEKLY]

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

A new building furnished with Baths and all modern Electrical Appliances for treatment was opened last Saturday, April 26th.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 1 grain of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures:—

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest.
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable. The Spa is under medical supervision and close co-operation is maintained with the patient's own physician.

Further particulars may be obtained at Belle Vue Spa or 7, Harley Street, W.1.

Apply: **The Secretary, Belle Vue Spa, Trefriw, North Wales.**

Telegrams: BELLEVUE, TREFRIW. Telephone: LLANRWST 60.

PROPRIETORS: **AMBULATORY TREATMENT LTD.**

C. A. HOEFFTCKE, Managing Director, 7, Harley Street, London, W.1.

By FRANK SCOTT FOWWEATHER, M.D., M.Sc., D.P.H., F.I.C., Lecturer in Chemical Pathology, University of Leeds.
12 Plates (10 Coloured) and 51 Text-figures. 15s., postage 9d.

CLINICAL PATHOLOGY
SECOND EDITION.
By P. N. PANTON, M.A., M.B., B.C.Cantab., Clinical Pathologist and Director of Hale Clinical Laboratory, London Hospital; and J. R. MARRACK, D.S.O., M.C., M.B., Chemical Pathologist, London Hospital.
With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms. 23s., postage 9d.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),
Senior Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.
Demy 8vo. Pp. 534.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

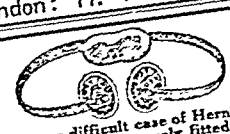
"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).



"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

THE CLINICAL JOURNAL.

SALTAIR SURGICAL SERVICE

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

SALT'S LONG EXPERIENCE IN SUPPLYING SURGICAL APPLIANCES FOR TROPICAL USE

has resulted in an ability to supply specially made appliances in all grades for all climatic conditions.

We therefore draw the attention of Medical Men to our

SPECIALLY LIGHT APPLIANCES FOR SUMMER WEAR

which not only afford the patient an exceptional degree of bodily comfort, but effect real hygiene and economy by allowing the winter appliance to be returned to us for cleaning and rehabilitation.

Excessive perspiration, which so quickly shortens the life of elastic goods, is avoided by the use of

SALT'S OPEN-WEAVE ELASTIC APPLIANCES.

STANIFORM

Regd. BRAND Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is counter-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I continue to get every satisfaction from 'Staniform' in the case of carbuncles, boils, whitlows, and all kinds of infected wounds."

"In a case of acute eczema on leg, the skin was quite normal within one week after starting application of 'Staniform Ointment.'"

"... left heel when first seen was about the size of a ... deal of pus. Foot much swollen—dressed with ... healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

SOLID IODINE

Safe—useful—portable

The manifold uses of H_2O_2 are known to all members of the medical profession. 'Peroxtik' is the only solidified form of Peroxide of Hydrogen in existence. Its utility, portability and safety is obvious, and every tube is guaranteed to maintain its original 10-volume strength for a reasonable period. Medical men interested in H_2O_2, who are desirous of testing 'Peroxtik,' should not fail to write for a free sample tube to ARTHUR H. COX & Co., LTD., 93, Lewes Road, Brighton.

'Peroxtik'

SOLIDIFIED PEROXIDE OF HYDROGEN

in neat, handy glass tubes.

Suppresses putrefaction and bacterial infection of the colon

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs. Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State. COATES & COOPER. 41, Great Tower Street, London E.C.3.

"ALMATA" KEEN'S COMPLETE FOOD for expectant and nursing Mothers

Sold by all Chemists 2/1 & 4/- per tin

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably FREE FROM THE IRRITANT AND NAUSEATING EFFECTS which are provoked by many preparations. There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract. The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Firienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

MONSOL *in* MIDWIFERY

An authority on the subject has expressed the considered opinion that the use of Monsol in midwifery would reduce the incidence of Puerperal Sepsis by fully 90 per cent.

Bacteriologists and Clinicians have proved repeatedly that Monsol has a selective action on Streptococci—an action ten times greater than lysol (which cannot destroy these germs except at a concentration liable to injure the tissues).

Outstanding features of Monsol are:

1. A high germicidal power against the organisms that cause sepsis.
2. A bland and emollient action—non-irritating to the tissues and mucous membranes at therapeutic concentrations.
3. Low toxicity. (One-sixth as poisonous as lysol.)
4. Great powers of penetration, reaching deep-seated inflammation.

Many Hospitals, Nursing Homes and Lying-in Institutions are now specifying the use of Monsol in all maternity cases. In addition to reducing the risk of infection, Monsol leaves the hands and skin soft and supple, a fact much appreciated by the Nursing Profession.

Monsol is the product of a Mond Laboratory, prepared under strict scientific control.

Monsol Toilet Soap 8d. Monsol Throat Pastilles 1/3 & 2/3. Monsol Dental Cream 1/-. Monsol Ointment 1/3 & 2/-. Monsol Liquid Germicide 2/-.

Local Anæsthesia in Surgical Practice

UTERINE PROLAPSE.

Typical Case.

Mrs. E. D. F., aged 53 years.

Diagnosis: Uterine prolapse, third degree, with large vesicocele.

Operation: *Watkin's interposition, perineorrhaphy.*

Anaesthesia: Classical infiltration block, using 45 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution in perineum. A circumferential block about the cervix was made, using 30 c.c. of the same solution. The patient noticed some distress during delivery of the uterus into the vagina. The round ligaments were blocked as soon as they appeared, 4 c.c. of Novocain-Adrenaline solution being used in each case. The classical Watkin's operation was performed. The perineum was then repaired by the split septum method. Anaesthesia was ideal. Patient's pulse was 80 at the end of operation, and she had no post-operative nausea, vomiting, or gas pains, and made an uneventful recovery.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

HOW GIBBS HELPS THE DOCTOR

Gibbs teaches the Golden Rule
PREVENTION IS BETTER THAN CURE

Prevention of decay is the keynote of all Gibbs advertising and propaganda. Gibbs try to teach the Public to regard the loss of even one tooth as a tragedy of the first magnitude.

By the constant reiteration of a few simple, wholesome precepts, Gibbs endeavour to impress strongly upon the Public the vital necessity for absolute cleanness of the mouth as a first principle in preserving the teeth. Following that, any authoritative utterances by Doctors or Dentists upon any phase of teeth preservation, are given the widest possible publicity by Gibbs.

The House of Gibbs welcome, at all times, suggestions from Doctors or Dentists as to any special phase of dental prophylaxis which, in the Doctor's or Dentist's opinion, should be specially emphasised at any particular time or in any particular locality.

Gibbs constantly remind the Public that a little care and thoughtfulness in matters of dental hygiene is repaid a thousandfold in returns of beauty, health, happiness and business and social success.

The Doctor and Dentist are always presented as the Highest Authorities upon all matters connected with the teeth. Very largely as a result of Gibbs propaganda, there is an increasing acceptance upon the part of the Public, of any and all advice or instruction given by the Medical Profession.

Thus, in so far as they are able, Gibbs are working hand in hand with the Doctor and Dentist, looking forward to that day when the greater part of all dental work will be purely preventive.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridge-work (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in anyway injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Gibbs Dentifrice

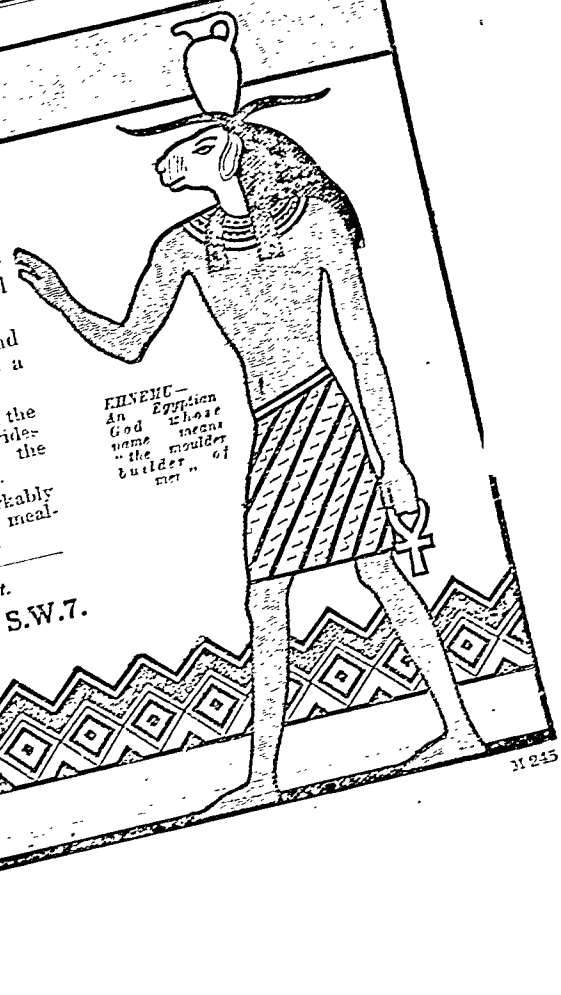
Literature, propaganda material, kinematograph films, leaflets, etc., as well as samples, are always freely at your disposal. Address: Dental Dept. 209wx, D. & W. Gibbs Ltd., London, E.1.

GD/Dr/1a

OVALTINE

FOR THE GROWING CHILD

"Ovaltine" is indicated as a means of promoting normal growth and development when the weight of the child under observation is less than that which statistics show a child of the same height should weigh.



The physician has only to consider the composition and properties of the product to recognize how suitable it is as a building and reconstructive nutrient.

"Ovaltine" is a concentrated extraction of malt, milk, and eggs in the form of golden brown granules. For tissue growth or repair it provides proteins, mineral constituents, adequate energy value, and the Accessory Growth Factors or Vitamins in correct nutritive ratio.

Children love the deliciousness of "Ovaltine" and thrive remarkably well upon this complete food. It is of unsurpassable value as a meal-time beverage in place of tea, coffee, cocoa, or other beverages.

A liberal supply for clinical trial sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, S.W.7.

PHTHAH—An Egyptian God whose name means "the moulder" or "builder" of men.

M 245

Mellin's Food
A MILK MODIFIER

MELLIN'S FOOD is specially prepared for modifying and adjusting cow's milk to meet the nutritive needs of infants deprived of human milk.

No matter whether certified, pasteurised, dried, or condensed milk is employed, its digestibility and its value as nourishment for the baby is enhanced by the addition of Mellin's Food. In other words, milk in any form is better borne, more completely utilised, and its nutritive constituents more appropriately balanced if properly modified with Mellin's Food.

There is no milk modifier exactly like Mellin's Food, and its continued recommendation by a large number of members of the Medical Profession is ample evidence of its outstanding advantages.

Further particulars and samples will be supplied on request.

"MODIFIED MILK IN INFANT FEEDING."

The above-named booklet of 64 pages will be gladly sent to members of the Medical Profession.

MELLIN'S FOOD LTD., LONDON, S.E.15

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W. Borchardt (*Deut. med. Woch.*, March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow, others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the red rib-marrow showed a definite increase of weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1.4 mg. per cent. The result was similar but more striking, the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years.

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture.

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

HANDFORTH LABORATORIES,
CLAPHAM ROAD, LONDON, S.W.9

The Treatment of
Chronic Affections
with CONTRAMINE

Many chronic affections, hitherto not amenable to treatment, are now found to respond to Contramine therapy.

Since chronic invalidity is a serious economic problem which has in the past defied satisfactory solution, this advance in chemotherapeutics is of vital importance.

Contramine is of particular value in the treatment of the chronic complications of gonorrhoea; it is recommended also in such chronic conditions as rheumatism, arthritis and fibrositis, whether of gonococcal origin or not.

Contramine is issued in ampoules ready for intramuscular injection; it is obtainable from all the leading chemists.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

M.C.14

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

Medisoap Therapy

The use of Medicated Soaps ensures the proper application of many drugs with the advantage of regular and frequent application, and at the same time attains adequate cleansing of the part. An interesting Brochure, indicating its uses in various skin diseases and describing Midgley's Medisoaps, will be sent on application.

℞. Medisoap Midgley No 10

When applied to the skin Ichthamol is partially absorbed, and has a stimulating and mildly irritant action in chronic skin diseases, such as acne and eczema. In addition to this useful action, it possesses antiseptic properties. Incorporated in a base of pure superfatted soap it makes available the use of a most valuable agent, possessing healing, sedative and tonic properties. One dozen trial samples (No. 10) sent post free for clinical use to any registered practitioner on application.

MEDISOAP ICHTHAMOL is prepared in three strengths:—

Mild (No. 59) 4% Standard (No. 10) 10% Strong (No. 96) 20%

Sole Makers:

CHARLES MIDGLEY, LTD. The Soap Specialists MANCHESTER

Associated with EVANS SONS LESCHER & WEBB, LTD., LIVERPOOL & LONDON.

"IODOLYSIN"

(TRADE MARK)

A Powerful Fibrolytic Agent

Gives strikingly successful results in many cases of rheumatoid arthritis and allied arthropathies.

Also employed with advantage for the removal of all other forms of pathological fibrous tissue.

It is a chemical combination of Iodine and Thiosinamin with these special features:

READY SOLUBILITY IN WATER. WELL TOLERATED. ABSENCE OF LOCAL REACTION ON INJECTION.

"Iodolysin" is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Free Clinical Sample and Literature on request.

Bowel Infection

in

DISEASES OF THE NERVOUS SYSTEM

A generation ago the origin of diseases of the nervous system presented for the most part a tangle of insoluble medical problems. The scientific worker of to-day, however, has so far cleared a way through the jungle as to make its ultimate conquest a certainty. In disorders of the nervous, as of other bodily systems, the overwhelming part played by toxaemic agencies has become generally recognised.

> "The first routine duty of the physician called upon to face nervous symptoms in which there is no known cause, such as arsenic, lead, or alcohol, is to search for a focus of infection. In some cases this will be found in the nasal cavity and its accessory sinuses, or in the mouth or pharynx, but in the great majority the seat of mischief lurks in the bowel. Should constipation and anaemia be associated with otherwise obscure nervous symptoms, there need be little hesitation concerning the diagnosis, and still less about the treatment. Bowel toxaemia proclaims itself in the boldest of type and the experienced physician often recognizes auto-intoxication at a glance. Happily, in all such cases, now that the problem of intestinal disinfection has been solved by the introduction of the benzene derivative Dimol, it is possible to clear out the immediate cause of the trouble *in situ*."
>
> ——, M.D.(Ed.), Cavendish Square, W.1.

A new era in the treatment of many diseases of the nervous system is thus opened up by the discovery of this benzene derivative. With the introduction of Dimol, the *bactericidal equivalent* of 140 grains pure phenol can be administered four or five times a day without affecting the mucosa or producing any toxic effect whatever.

Samples and Literature will be sent on application to the

Dimol Laboratories, Limited, 40, Ludgate Hill, London, E.C.4

Regesan

CREAM OF MAGNESIA with LIQUID PARAFFIN

(Contains 30% Liquid Paraffin).

A stable well-balanced combination containing 30% Liquid Paraffin held in suspension in a finely divided state. Its consistency is such that the tendency to leak exhibited by Liquid Paraffin is eliminated.

Regesan Cream of Magnesia with Liquid Paraffin provides suitable treatment for all digestive troubles with which constipation and hæmorrhoids are associated. It is certainly the ideal laxative during pregnancy and lactation, and most suitable for infants and children.

Price 1/6 per bottle.

Full-size trial package free to Medical Practitioners in the British Isles on application to Boots the Chemists, Station Street, Nottingham.

(Aesculapius)

HYPERACIDITY

In the treatment of hyperacidity, the orthodox method of neutralising with alkalis is accompanied by certain unpleasant sequelae, such as the evolution of gas in the stomach. Another method is to utilise the phenomenon of adsorption, in which the acid is adsorbed on some substance without being chemically neutralised.

COLLUMINA

A special Colloidal Aluminium Hydroxide prepared by a process evolved at Evans' Biological Institute is peculiarly adapted for this purpose. COLLUMINA absorbs the acid without splitting it up, and thus obviates its painful effects without unpleasant results.

In addition to its neutralising effect upon hydrochloric acid

COLLUMINA

is a mild astringent and deodorant, thereby presenting usefulness in the relief of congestion of the mucous linings of the mouth, pharynx and stomach, and although mildly astringent is soothing. It is non-toxic and, being pleasantly flavoured, finds a wide range of usefulness varying from conditions of genuine organic disturbance to hypochondriacal conditions.

COLLUMINA is supplied as the plain colloidal preparation of aluminium, and also combined with phenolphthalein, for cases of intestinal stasis, and with bismuth for cases associated with intestinal colic and diarrhoea.

Sample and literature on application to—

Evans' Biological Institute, Runcorn.

PART OF A STATUE BELIEVED TO BE THAT OF THE EMPEROR JULIAN.—At the command of the Emperor Julian, his Court Physician, Oribasius, compiled a medical encyclopædia. Whilst the Byzantine physicians contributed little that was original to medical science, they performed valuable service to the cause of medicine by collecting, during a period of stagnation, the works of their great Greek predecessors. Thus the work of the classical medical authors was preserved for posterity. Oribasius, who was one of the most important of these collators, obtained what was best not only from Galen but from many medical authors whose names would not now be known but for him. This material he collected and classified "that physicians might find rapidly that remedy which in each case should be suitable to the patient," and issued as his "Collecta Medicinalia" an encyclopædia in 70 volumes. Oribasius always cites his authorities. Many of the volumes have been lost, but sufficient remain to excite admiration for this exact, reverent compiler. Later, Oribasius compiled his Synopsis, a short work in 9 volumes for the use of his son, a medical student.

A Lecture
ON
ILEUS: ACTIVE AND PARALYTIC

DELIVERED TO THE HAMPSTEAD MEDICAL SOCIETY ON JANUARY 16TH, 1930,

BY

H. TYRRELL-GRAY, M.A., M.Ch.Cantab., F.R.C.S.,
SURGEON TO THE WEST LONDON HOSPITAL, THE HOSPITAL FOR SICK CHILDREN, ETC.

"ILEUS" was thus described by Barnard[1]: "an ancient term incapable of precise definition, and therefore should not be used." In our everyday practice, however, this title outlines to all of us the picture of a motionless distension of the intestine in the absence of any obstructive lesion.

There are two main causes of intestinal distension:

1. *Obstruction* to the passage of contents is associated with overaction and hypertrophy.[2] Clinically peristalsis is seen and felt.

2. *Inertia* of the intestinal muscle from (*a*) active inhibition, and (*b*) interference with the circulation; either ultimately leading to distension.

Intrinsically the distinction is so sharp, both clinically and pathologically, that I submit the following definition of "ileus": "Distension from intestinal inertia."

Four factors are concerned: (*a*) an organ of independent functioning power (even when removed from the body),[3] co-ordinated and controlled for the needs of the body by (*b*) *sympathetic nerves*—inhibitory to bowel movements and vaso-constrictor to the arteries; (*c*) *parasympathetic nerves*, whose stimulation excites intestinal motility; and (*d*) the blood supply of the intestine. The co-ordination of these constitutes a physiological balance.

It is generally recognized that ordinary simultaneous stimulation (whether experimental or pathological) of these antagonistic nerves always leads to a domination of the sympathetic or inhibitory group,[4] and a motionless intestine results.

Now in the etiology of ileus (or "inertia distension") at least four primary types demand consideration: (*a*) the effect of bacterial toxins on the bowel wall; (*b*) mechanical obstruction; (*c*) "active ileus"; (*d*) "paralytic ileus."

The Effect of Bacterial Toxins on the Bowel Wall

The observation of active intestinal movements after death from "ileus" (Nothnagel)[5] would appear to exclude this as a cause.

Mechanical Obstruction.

As an example, in carcinoma of the colon, the stage of overaction and hypertrophy signifies an effort to drive the

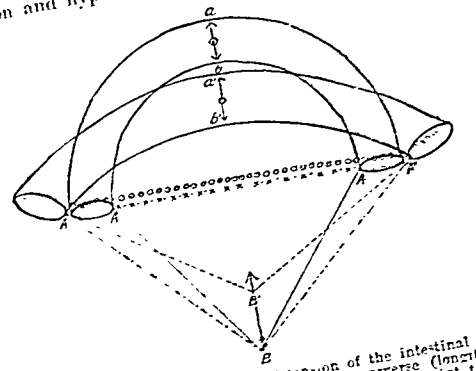

FIG. 1.—*a-b*, *a'-b'* represent the distension of the intestinal lumen; A-A and A'-A' represent the increase of transverse (longitudinal) mesenteric tension; B, fixed point of mesentery; B', point to which mesentery would be dragged if it were not *fixed*; B-A and B'-A', being equal, B-A' and B-B' show vertical *mesenteric* tension.

"inert area" of the intestine down the intestinal tract. The ultimate compression of the congested and swollen mucosa into the narrowed lumen completes the picture of final obstruction. The gradual transition from the "active" stage to "intestinal inertia," with the typical cachexia, is attributable to two factors: (1) compression of capillaries and veins in the intestinal wall. This leads to increasing failure of intestinal muscle. (2) Tension on the mesentery in two directions (Fig. 1). Mesenteric tension was recognized by Nothnagel[5] and Barnard,[1] and I have demonstrated it experimentally.

Here I must remind you that increase of pressure in a bent tube tends to straighten it; and that, owing to the increased length of the intestine over that of its mesenteric attachment, the same law holds good for the gastro-intestinal tract.

Increased mesenteric tension has two results:

(*a*) Mechanical stimulation of the contained sympathetic fibres, and the resulting inhibition of intestinal movement.[3]

(*b*) Tension on, and obliteration of, the most collapsible structures—that is, mesenteric veins.[10] This leads to venous stasis and paralysis of intestinal muscle.

These last two factors can each, separately or conjointly, institute intestinal inertia or "ileus" by a different mechanism. Accordingly there are two varieties to be recognized.

"Active Ileus."

This is intestinal inertia excited by sympathetic inhibitory impulses, and it is conveniently illustrated by the example of acute inflammation of the appendix adjacent to the ileal mesentery ("five o'clock appendix").

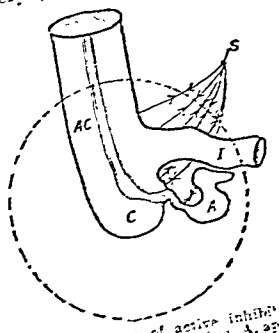

FIG. 2.—Diagram of the area of active inhibitory nerve impulses (afferent and efferent) in acute appendicitis. A, appendix; C, caecum; I, ileum; AC, ascending colon; S, sympathetic nerve supply to the inflamed area. Dotted line = extent of *direct* intestinal inhibition.

In sharp contradistinction to the retrocaecal or pelvic appendix, it is in this situation (Fig. 2) that acute appendicitis is associated with the classical symptoms from the onset, by reason of the mesenteric reflexes it evokes. Such a lesion stimulates in the immediate neighbourhood (Fig. 2):

(*a*) The efferent sympathetic. Intestinal movement is inhibited in the dotted area.

(*b*) The afferent sympathetic. The efferent response evokes: (i) proportionate immobility of the whole intestinal tract; and (ii) proportionate closure of the pylorus against the passage of food.

(*c*) The afferent vagus. The resulting contraction of the proximal stomach against a closed pylorus empties this viscus of food.

The whole picture of the empty stomach and motionless intestine is that of a protective mechanism. It is to be regarded as a physiological response to injury or infection; as a mechanism designed to immobilize and rest the inflamed part; to prevent the ingestion of food; and to localize the inflammatory process.

One further protective mechanism is evident. The presence of Paccinian (or touch) corpuscles in the mesentery—long recognized—was emphasized years ago by Keith.[11] He described them as "end organs for receiving pressure." Their stimulation excites the reflex immobility of the abdominal wall—again a protective mechanism. The whole protective picture is proportionate to the extent of the exciting cause—clearly the resulting distension may reach a sufficient degree to interfere with the venous return, and so to initiate the onset of "paralytic ileus."

"Paralytic Ileus"—Intestinal Inertia of Circulatory Origin.

A classical example is that of "acute intestinal strangulation," in which the importance of the circulatory factor was recognized by Barnard.[12] This is a clinical analogy to the experimental ligature of the intestinal veins with the arteries intact. The result is:

(i) Severe stimulation of the Paccinian corpuscles, leading to shock,[13] vomiting, and initial immobility of the abdominal wall.

(ii) As soon as the pressure in the obstructed veins exceeds that in the intestinal lumen, gases pass from the blood into the viscus by osmotic pressure, and progressive inertia and distension begin.

(iii) When in due course the pressure in the bowel exceeds that in the veins, gases will pass by osmosis back into the blood stream; and these, exhaled by the lungs, will give a faecal odour to the breath—a most significant diagnostic symptom. The progressive extension of mesenteric tension so induced leads to a proportionate spread of venous engorgement, and thus:

(iv) Fluid from the veins passes, not only into the peritoneum, but into the intestinal lumen. In due course absorption of fluids and gases from the bowel accentuate the initial shock with a profound toxaemia. Such a process, if unrelieved, is essentially progressive; so that, when the gastric musculature is involved and failure of the pyloric sphincter occurs, the intestinal contents obtain access to the stomach, and the result is stercoral vomiting. The condition is now analogous to that seen in "acute dilatation of the stomach."

(v) *The ileo-colic sphincter.* Normally the large bowel is adapted to tolerate a degree of intermittent obstruction, created by the voluntary control of the anus. From this the small intestine (which is not so adapted) is protected by the ileo-colic sphincter. This Elliott[14] showed to contract as the result of sympathetic stimulation, anaemia, and adrenaline. (That this function of the sphincter is of importance is shown by the changes in the ileum following colectomy—changes which are hardly noticeable after a year, when the same operation is performed by implanting the ileo-colic sphincter into the sigmoid and so preserving its function.) Whereas, then, the ileo-colic sphincter is closed in "active ileus" (from sympathetic stimulation), it will, in common with the rest of the intestine, be paralysed by venous engorgement. The free access of the infective contents of the colon to the small bowel may be one of the reasons for the highly increased "infectivity" of the contents when intestinal paralysis follows venous obstruction.

Clearly severe toxaemia and faecal odour of the breath are not features of "active or protective ileus," but are evidence of venous stagnation and "paralytic ileus." In minor degrees such ileo-colic incompetence may play a part in chronic disease. Further, if this picture is correct, the absence of toxaemia in obstruction (when the venous return is unimpaired) is in sharp contrast to the rapid toxaemia of strangulation, due to the obstructed venous return.

The clinical lesson stresses the significance of the breath as an indication of intestinal derangement associated with a defective venous return.

(vi) *The abdominal wall.* Increase of intra-abdominal pressure, by further compression of the larger veins, accentuates venous stasis. Accordingly "paralytic ileus" tends to occur sooner in subjects who are stout, or have firm abdominal walls, than in those with flabby muscles. For instance, it is remarkable to see the degree of distension which sometimes follows Caesarean section without marked distress or constitutional symptoms.

PRACTICAL ISSUES.

The clear-cut distinction between these two forms of ileus—active and paralytic—should form the foundation of our clinical practice. Accordingly we recognize two main groups of primary exciting causes of intestinal inertia and subsequent distension: (*a*) extra-abdominal; (*b*) intra-abdominal.

A.—*Extra-abdominal.*

A brief reference only to some of the more important conditions which may confuse or aggravate the clinical picture is possible.

1. *The Psychic Factor.*—Excessive or prolonged sympathetic stimulation of psychic origin inhibits both secretory and motor functions of the gastro-intestinal tract. In acute forms cessation of intestinal movement was recognized by Cannon,[15] Leonard Hill,[16] Langdon Brown,[17] and many others. In milder form such derangements may result from excessive mental activity; anxiety and apprehension; fear; unhappiness, etc. If long-continued, the gastro-intestinal sequelae may become permanent, and so accurate diagnosis of the primary disease may be exceedingly difficult.

2. *The Pulmonary Factor.*—Abdominal distension associated with pneumonia and empyema is a common experience, especially as a terminal feature. Mannaberg[18] believed it to be due to peritonitis (that is, infective agencies), but it is probably circulatory in origin.

3. *Cardiac.*—Heart failure has long been recognized as a cause of venous stasis in the viscera (Nothnagel, loc. cit.) and consequent distension.

In both the latter groups the absence of that characteristic odour of the breath constitutes an important clinical distinction.

4. *The Renal Factor.*—This factor (in renal colic, for example) induces an "active" or inhibitory ileus by sympathetic stimulation. Again the odour of the breath in addition to the history, etc., is a useful guide unless the circulatory type—"paralytic ileus"—supervenes.

A striking example came under my notice last summer. I operated on a man of 51 years for pain and repeated vomiting, absolute constipation associated with an enormous degree of abdominal distension, and visible coils of gut. No gross lesion of the alimentary tract could be found, but he had a haemorrhage into a left hypernephroma, which I subsequently removed, when the distension subsided as the result of a temporary caecostomy.

B.—*Intra-abdominal.*

Post-operative Ileus ("Paralytic Ileus").—I have long believed (and invariably acted on the belief) that if we would aid (and, if necessary, supplement) Nature's methods of immobilization and rest of the gastro-intestinal tract after laparotomy, this dreaded sequel would be excessively rare. The mechanism is the same for trauma as for infection, both of which, as we have already seen, primarily evoke local and general immobility by direct and indirect sympathetic stimulation. This, as already stated, results from injury to the mesentery and also to the parietal peritoneum. The stimulation of the contained Paccinian corpuscles further immobilizes reflexly the abdominal wall.

This picture of a protective mechanism is designed to ensure rest, and should be the basis of our treatment, characterized largely by masterly inactivity. "Active" (physiological) ileus is to be promoted by various measures.

Starvation.—Common sense indicates a middle course between absolute starvation of fluids and plethora. The former induces restlessness and misery from thirst, and violates the principles of rest, both bodily and psychic. The latter may induce vomiting and flatulence. A medicine glass of fruit juice stood at the bedside and sipped at will, or chewing fruit (for example, pineapple, grapes, etc.), will suffice to check thirst, clean the mouth, and supply carbohydrates.

Rectal salines (less irritating and more easily retained than water) with 5 per cent. glucose, at approximately four-hourly intervals, are less disturbing than continuous proctolysis.

The Fowler position is adopted for two reasons: (*a*) relaxation of the abdominal muscles adds to comfort; (*b*) gravitation of peritoneal fluid to known regions (Box[19]) and the more innocuous sites.

Sedatives.—Local and general rest are promoted by sleep. Blood pressure tracings during the exhibition of emotions (anxiety, apprehension, fear, etc.) so closely approximate those seen in the initial stages of shock that, for these reasons, for personal comfort, and for humanitarian purposes, the liberal administration of morphine (or its allies) is an essential routine.

I have in mind a medical man (intent on analysing his symptoms) who developed, after operation for obstruction, an alarming degree of distension of from four to five days' duration, relieved only by liberal administration of morphine and radiant heat to the abdomen.

Purgation and Feeding.—Diverse practice and teaching on this point are evidence that current views are based on empyrical rather than scientific grounds. There is no

general rule. The subsidence of an inflammatory or traumatic lesion is evidenced by a return of intestinal movement. Clinically this is ascertained by the patient; the use of the stethoscope; and the spontaneous passage of flatus. These constitute a demand (whenever they occur) either for temporary assistance by pituitrin injection and turpentine washouts, or for initiating a normal routine with a purgative followed by a gradual return to normal diet—each case being considered on its merits. The former is a temporary measure which can always be employed to prevent or relieve a distension which may threaten to become, in itself, a source of distress. The momentary effect is a negligible violation of the principle of rest. Purgation, if adopted before there is evidence of a return of intestinal activity, only causes hyperaemia, outpouring of fluids and gas into the intestines, and distension. Finally it may actually precipitate the onset of "paralytic ileus." Accordingly adherence to principle will forbid the administration of a purgative until there is evidence of the return of intestinal activity.

"Paralytic Ileus."

It is evident that distension arising from physiological ileus may, in any case (often as a result of mismanagement), reach a degree sufficient to compress the veins, and initiate paralytic ileus—in any instance this may be accentuated by cardiac failure, pulmonary complications, etc., as already stated. The odour of the breath, the state of the tongue, and the constitutional changes are all evidence of the onset of venous obstruction and the interchange of gases referred to. Measures for prevention are, in part, measures for cure. Accordingly we should add the following to the routine outlined.

Radiant heat to the abdomen—recommended to me many years ago by Sir George Makins—has formed so integral a part of my routine that my own nursing sister applies it to every case until it can evidently be dispensed with. To its routine employment I attribute a relative immunity from serious "paralytic ileus." Its action is to reduce deep congestion by causing superficial hyperaemia.

Cardiac insufficiency and pulmonary complications—both of which have been discussed as potentially initiating or accentuating venous obstruction—must be watched and controlled. The injection of strychnine 1/30 grain, atropine 1/100 grain, adrenaline (1 in 1,000) 10 minims (sometimes called the A.S.A. (or Trinity) hypodermic of Boyd), given six-hourly for four doses (and repeated in half doses if necessary), is an excellent precautionary measure. With its employment the pulse rate and thirst must be watched and controlled.

Progressive "Paralytic Ileus."

Nothnagel's[20] observations would appear to contradict the theory of Reichel,[21] that ileus is due to bacterial invasion of the bowel wall. Accordingly clinical methods, directed towards the restoration of intestinal motility, should be concentrated upon the relief of distension and intra-abdominal pressure. Interval injections of pituitrin followed by turpentine or human bile washouts promote a diminished intra-abdominal pressure, and so a restoration of intestinal circulation.

Gastric lavage further reduces abdominal distension and favours the return to a normal circulation. This measure (which appears never to be harmful) is urgently indicated when vomiting has commenced.

Avoidance of purgation.—It has been pointed out that intestinal inertia is only accentuated by purgation—morphine (or an allied sedative) is indicated. I have in mind an instance of an over-anxious doctor administering 1 grain doses of calomel hourly to a lady during the stage of post-operative protective ileus. The resulting picture of acute obstruction was relieved by morphine and radiant heat to the abdomen.

I must emphasize the rule that the only sure indication for purgation and feeding is evidence of the return of normal intestinal activity.

In the rare instances when this routine is ineffective a light general anaesthetic should precede a spinal anaesthetic. This may result in a copious evacuation, from the removal of inhibitory reflexes. If this occurs after the abdomen is open (and mechanical obstruction is excluded) a catheter passed per rectum as high as possible is sufficient. Otherwise a temporary ileostomy or jejunostomy (by Witzel's method) is indicated. The initial discharge of faeces from this procedure is usually followed by an absence of drainage for twenty-four to thirty-six hours—a feature which often causes unnecessary anxiety to those in charge.

The explanation is that the relief of pressure (and the consequent return of normal circulation) spreads consecutively from loop to loop of intestine, and is associated with a gradual spreading return of intestinal activity. This is a relatively slow process. Initially purgation only increases ileus; morphine and radiant heat are indicated to ensure rest, diminish secretion, and relieve congestion. To mention a striking example:

A woman, aged 40, had a gangrenous appendix removed and the pelvis drained. Acute obstruction supervened on the tenth day. A second operation released the volvulus round the tube sinus, and temporary ileostomy was followed by a copious evacuation. Subsequently there was little drainage for forty-eight hours. It was ascertained that pituitrin injections, enemata, and purgation had been persisted in during this period, and were only followed by increasing distension. This yielded immediately to radiant heat and the liberal administration of morphine, which gave sleep and led to natural actions of the bowels and the subsequent automatic closure of the fistula.

Intermittent and Chronic Ileus.

So far viscero-motor reflexes (in their physiological or protective capacity), and circulatory (pathological) defects arising from trauma or infection, have been considered only in acute form. It is not difficult to envisage analogous symptoms arising from milder or more chronic lesions of similar character.

1. *Inhibitory Impulses in Chronic Disease.*

If the symptoms of acute inflammation of the "five o'clock" appendix be again referred to, and be modified to those of chronic disease arising either from inflammatory or mechanical agencies, it is not difficult to substitute: (*a*) flatulence and anorexia for vomiting; (*b*) constipation requiring laxatives for general intestinal inhibition; and (*c*) discomfort and referred pain from acute epigastric pain becoming localized to the inflammatory area.

In chronic or intermittent form such symptoms are only a mild but faithful mimicry of the acute crisis. As an analogy the flatulence, distension, and constipation associated with gall-bladder disease are referable to the same type of reflex; examples might be multiplied.

2. *The Circulatory Factor in Chronic Disease.*

It is important to realize that—the portal system being devoid of valves—the vasomotor tone, the support of the abdominal muscles, and the negative pressure of the thoracic inspiration are all factors of importance. This was realized by Leonard Hill and Barnard[22] when, discussing a flabby abdominal wall, they referred to "the abdominal vessels . . . similar in nature to an easily distensible bag."

Keith[23] realized the importance of the abdominal muscles in effective expansion of the lungs when, twenty-seven years ago, he described the diaphragm as an "abdominal piston" in the "abdominal type of respiration," in contradistinction to the normal "thoracic type" with efficient abdominal muscles.

Abdominal venous stasis, associated with the resultant intestinal inefficiency, is gradually initiated by: (*a*) pooling in the abdominal veins—the result of imperfect tone of the abdominal wall; and (*b*) insufficient negative thoracic pressure—due to an inefficient expansion of the lower lobes of the lungs (an important factor in pulmonary complications following "upper abdominal" operations). In chronic disease remedial breathing instruction has been beneficially emphasized by MacMahon.[24]

3. *Inhibitory and Circulatory Factors Combined.*

This is most conveniently illustrated by the congenital mobile colon, but, in preface, it is only fair to insist that the actual position of the colon means nothing whatever. What is really important is its means of support in the upright position.[25] The mesentery is *not* (and never was designed as) a supporting structure. As a result of this pathological imposition there are two results:

(*a*) Sympathetic inhibitory stimuli (with consequent general stasis, flatulence, etc.)—a mild mimicry of the mechanism and symptoms already portrayed in the picture of acute appendicitis (Fig. 2).

(*b*) Again the most collapsible structures suffer first. The resulting tension on the mesenteric veins leads to venous stasis (evidenced clinically by the tortuous arteries so commonly seen during operations on these subjects), and accentuates the existing intestinal inefficiency due to inhibition (Fig. 3). In subjects of visceroptosis these two factors combine to produce the symptoms which are in the experience of us all.

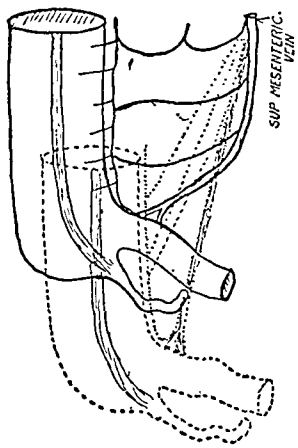

FIG. 3.—Showing tension on mesenteric vessels and concomitant sympathetic fibres in coloptosis.

As an example, we are all familiar with the patient of sturdy athletic build, with well-fixed colon, who suffers no symptoms from (or clinical evidence of) constipation, even if this extends over several days. A similar constipation in the subject of visceroptosis leads to fetor of the breath, discomfort and distension, flatulence, anorexia, etc. Is not this comparison again a mild mimicry of the picture we have already considered when we contrasted the absence of constitutional symptoms associated with chronic obstruction with the profound changes seen in strangulation? Can it be doubted that the venous factor is equally responsible for the symptoms in chronic mesenteric tension (visceroptosis) as it is in acute strangulation?[10]

Again, the end-result of venous stasis and the temporary intestinal inefficiency which results, ultimately is fibrosis. Fibrosis not only involves the muscle, but, far more serious, may (and in long-standing cases undoubtedly does) involve Auerbach's plexus, thereby dislocating the whole neuromuscular mechanism of the intestine.[4]

Surely it is our duty to anticipate this eventual and incurable sequel of venous stasis by imitating Nature's normal method of mesenteric fusion, and performing the simple operation of colopexy, in suitable cases. The success of such a procedure, carried out on sound principles, depends on the selection of cases for operation; and, from what has been said, this is often no simple problem.

In conclusion, it is submitted that the term "ileus" should present to us a picture of intestinal inertia of two types: (1) active ileus—a physiological and defensive mechanism due to inhibitory nervous impulses; and (2) paralytic ileus—a pathological and progressive condition due to venous obstruction.

In chronic form the symptoms are a mild mimicry of those we are familiar with in acute abdominal crises; but the principles on which treatment should be based are identical—namely: "active (physiological) ileus" should always be imitated and supplemented; while every effort should be directed towards the prevention of increased venous pressure (from any source) and the possible onset of "paralytic ileus."

URGENT UTERINE HAEMORRHAGE OF CONSTITUTIONAL ORIGIN.

BY

ALBERT SHARMAN, B.Sc., M.B., CH.B.,

McCUNN RESEARCH SCHOLAR, AND SURGEON, OUT-PATIENT DEPARTMENT, ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.

LOCAL or pelvic causes account for by far the majority of cases of abnormal uterine haemorrhage, which, according to Beckwith Whitehouse, may be classified into four groups: epimenorrhoea (menstrual periods too frequent), menorrhagia (periods profuse), menostaxis (too prolonged), and metrostaxis (irregular bleeding). Minor degrees of any of these conditions are occasionally met with associated with constitutional disturbances or disorders of metabolism, such as myxoedema, exophthalmic goitre, acute infectious diseases, and the anaemias. Shaw,[1] in his very detailed work on irregular uterine haemorrhage, has noted that in 17.5 per cent. of his series of 200 cases of excessive uterine haemorrhage no explanation for its etiology could be offered. He states that it is always extremely difficult to attribute menstrual abnormalities to general metabolic and endocrinal disturbance, for in the majority of cases there is no obvious association, and it is undoubtedly true that, in the past, any association that there may be has been grossly exaggerated. He admits that it is possible that in many of the 200 cases investigated some such conditions have been present. Schmitz,[2] in a survey of 2,184 consecutive hospital records and 2,126 records of out-patients, found that about 36 per cent. of them complained of uterine haemorrhage. No diagnosis as to the cause of the bleeding was made in 22 cases of the in-patient series and in 23 cases of the out-patient series. Linton, Marks, and Smith[3] remark that possible factors in the etiology of abnormal flowing without demonstrable pathological conditions are, among others: local or systemic endocrine dysfunction, subclinical constitutional blood disease, and systemic blood disease. According to Munro Kerr,[4] the common blood diseases, such as anaemia and chlorosis, are associated with amenorrhoea; far more grave disorders, such as scurvy, purpura, etc., are generally accompanied by menorrhagia. Gow is quoted as having shown, in a study of mitral stenosis, that in about 20 per cent. of cases only was menorrhagia present, despite the hitherto general belief that the two conditions were associated. Munro Kerr states that haemophilia is a possible cause of uterine haemorrhage, but Osler[5] quotes Bulloch and Fildes's claim to have established the fact of immunity in females and their denial of the authenticity of all the published cases. In Grandidier's series of 334 cases of haemophilia uterine bleeding was not instanced. Meigs[6] has described a few interesting and unusual cases of benign uterine bleeding, excluding the usual causes, such as fibroids, inflammation, polypi, etc. They fell under the following headings: hyper-

thyroid, hypothyroid, pituitary disorder, thrombopenic purpura haemorrhagica, atypical purpura haemorrhagica, endocrine, and cases with no definite pathological findings. Possibly, in many clinical cases of mild or moderate uterine haemorrhage a general cause is overlooked. When bleeding is severe it almost always has a local cause.[7]

Profuse uterine haemorrhage, severe enough to endanger life and of constitutional origin, is undoubtedly uncommon, and in a review of approximately 19,000 in-patient records (from 1920 to 1930) in the Royal Samaritan Hospital for Women, Glasgow, I have encountered only seven cases of such a category. The main features of these cases are detailed below.

CASE I.

This girl, aged 15 years, was admitted urgently to hospital on February 22nd, 1921, suffering from profuse haemorrhage from the vagina. It was of sixteen days' duration, and hitherto she had not menstruated. Bleeding was continual, and had necessitated her remaining in bed. On examination she was found to be blanched, the lips, gums, and conjunctivae being almost colourless; she was poorly nourished, and haemic murmurs were present. No pelvic abnormality was detected on rectal examination.

Four years previously purple spots appeared one day "under the arms and breasts." On the following day epistaxis commenced, and was accompanied by sickness and vomiting. On two further occasions, at two-monthly intervals, nasal bleeding recurred. It was noticed by her mother that, prior to each haemorrhage, the patient became excited, and there was apparently involuntary blinking of the eyes. Each attack of epistaxis lasted about twenty-four hours and ceased spontaneously. Since 1917, too, successive crops of purple spots appeared and disappeared, and on one occasion there was some diffuse purple discoloration of the legs; there was no history of trauma, and there was no history of "bleeders" in the family.

Blood examination: The red cells numbered 1,600,000 per c.mm., the white cells 30,000. Polychromatophilia, poikilocytosis, and nucleated red cells were seen.

On March 8th she was transferred to Glasgow Victoria Infirmary for medical treatment. On admission she was blanched, breathing was shallow, the pulse small and weak, and she complained of thirst. She was given subcutaneous and intravenous salines. No abnormal constituents were present in the urine. On the following day she was examined under light general anaesthesia, and the uterus and appendages were found to be apparently normal. The cervix was dilated and the uterus curetted. She was given pituitrin (1/2 c.cm.) four-hourly, and 3 ounces of saline containing 30 grains of calcium lactate, four-hourly, per rectum; this was continued for seventy-two hours. For three or four days after admission she rallied, but then became delirious and developed gangrene of the right foot and of the toes of both feet. For ten days she was given, by the mouth, a mixture containing the chloride, lactate, and iodide of calcium. However, her condition became worse, and she died on March 20th—that is, six weeks after her first uterine haemorrhage commenced. Post-mortem examination revealed no features of note.

Unfortunately a detailed blood examination, including platelet count and bleeding time, was not carried out in this case, but from the history a presumptive diagnosis of thrombopenic purpura haemorrhagica may be made. Price[8] states that in purpura haemorrhagica, menorrhagia in the adult is frequent and is a dangerous symptom. Meigs's[6] case of this condition was that of a girl, aged 14 years, who had had four transfusions to stop nasal bleeding. Later, she had continuous uterine haemorrhage for three months, at the end of which her haemoglobin was 35 per cent. Transfusion and splenectomy were performed. Two days later the platelets and bleeding time were normal, and uterine bleeding stopped almost at once. Her periods subsequently were normal and regular. Linton, Marks, and Smith[5] report the results of treating by radium a series of 250 cases of uterine bleeding not due to malignant disease. One case (a young girl) in this series was due to idiopathic thrombopenic purpura, and was treated by three local radium applications and intensive ultra-violet ray treatment over the spleen; she is now apparently well, nine years after her first admission.

CASE II.

A girl, aged 14 years, was admitted to hospital on May 25th, 1922, as an urgent case of profuse uterine haemorrhage. Bleeding had commenced ten weeks previously, and had continued without interruption. On examination she was blanched, the pulse rapid, and the heart sounds soft but pure. The only feature of her past health was that "she had always been anaemic."

She was given elixir calcium chloride, 1 drachm thrice daily, and the foot of the bed was elevated. Two days later the pulse was still rapid and very poor in quality, and rectal salines were administered. Her condition remained serious for several days, but, when improvement showed, she was examined per rectum under anaesthesia, and no gynaecological abnormality was detected.

Blood examination (ten days after admission): The red cells numbered 4,775,000 per c.mm., white cells 11,875; haemoglobin 45 per cent.; colour index 0.47. The erythrocytes were pale in colour, and a few nucleated red corpuscles were seen. There was some poikilocytosis. No myelocytes were present, polymorphonuclear leucocytes predominating.

The diagnosis in this case was that of chlorosis. The usual medical treatment was employed, and she was dismissed well on June 23rd, 1922.

Almost eight years later (May 9th, 1930) I saw this patient, and was informed that periods had been normal and regular for several years. She was of small stature and generally underdeveloped, her appearance suggesting that she was still very anaemic. I examined her blood, with the following results: red cells 4,500,000 per c.mm., white cells 7,800; haemoglobin 50 per cent.; colour index 0.5. The erythrocytes were pale in colour, and "ring-staining" was marked. There was some poikilocytosis. No nucleated red cells or anisocytosis were present. No myelocytes were seen, polymorphonuclear leucocytes being in normal proportion. The blood picture, it is interesting to note, was still of the chlorotic type.

CASE III.

A patient, aged 45 years, was admitted to hospital as an urgent case on April 29th, 1924, complaining of very profuse menstruation. For twelve months prior to admission menstrual periods had been very irregular; her three most recent ones had extended for five to seven days, bleeding being very profuse and large clots being passed. On examination she was found to be very pale and the pulse thready; systolic murmurs were present at the apical and aortic areas of the heart.

Puberty was at 12 years of age, and menstruation had been regular and normal until the age of 44. With the exception of a slight attack of pleurisy, her past health had been good.

Blood examination: The red cells numbered 3,300,000 per c.mm., white cells 10,400; haemoglobin 60 per cent.; colour index 1.2.

Two days after admission she was examined under general anaesthesia; the uterus was dilated and curetted and the curettings examined microscopically. A small mucous polyp was found, but neither in it nor in the endometrium was there any evidence of malignancy. On the day following operation she developed phlebitis of the left leg. Three days later her condition became critical, and despite liberal stimulation and treatment with brandy, digitalin, strychnine, and salines, she died on the eighth day after admission to hospital.

Unfortunately a more detailed blood examination was not made in this case, and a suggested diagnosis of pernicious anaemia could not be made with certainty.

CASE IV.

This patient, a woman aged 43, was admitted to hospital on April 21st, 1926, as an urgent case of uterine haemorrhage. Bleeding per vaginam had been constantly present for the preceding three weeks, and for four days prior to admission had been extremely profuse. An ergot mixture from her physician had made no appreciable difference. She was found to be exsanguinated and in a critical condition. Her temperature was 96.4°, pulse rate 100, and respirations 20 per minute. Examination of the pelvis revealed no local or pelvic abnormality.

The patient had suffered for several years from "internal bleeding piles." There was also a history of myxoedema three years previously, and for this she had had thyroid treatment, which had latterly been discontinued. She had been married sixteen years, had five children and no miscarriages, and labours and puerperia had been uneventful. The menopause was eighteen months prior to her urgent admission to hospital, and in this interval there was no uterine bleeding whatever.

Blood examination: The red cells numbered 960,000 per c.mm. A blood film showed a polymorphonuclear leucocytosis; the red cells were of normal shape, and no poikilocytosis or nucleated red cells were present.

The patient was treated with the usual measures for the arrest of bleeding per vaginam, and rectal salines were administered. Her condition, however, became worse, the pulse became weaker, and she died four days after admission to hospital. A post-mortem examination was refused.

The features of this case were: (1) eighteen months of complete amenorrhoea and apparently normal health after the menopause: (2) one attack only of severe uterine haemorrhage (this proved to be fatal): (3) a history of myxoedema; and (4) an extremely low red blood cell

count and a normal film. (Unfortunately, for some reason not apparent, the haemogobin percentage was either not estimated or not noted.)

CASE V.

This patient, who was 27 years of age, was admitted to hospital on May 14th, 1928, with a complaint of very profuse haemorrhage per vaginam. Three weeks previously a menstrual period commenced, and for the first twenty-four hours was accompanied by epistaxis. Severe uterine bleeding continued throughout three weeks. On examination she appeared almost exsanguinated. The urine contained much albumin.

She had had scarlet fever during childhood. When 20 years of age she was a patient in Glasgow Royal Infirmary, and was under treatment for nephritis. For three years prior to the attack of menostaxis, oedema of the face and legs was absent, but albuminuria was constant. Since puberty menstruation had been scanty but regular.

Her condition improved with general measures and rest in bed. No abnormality was detected in the pelvis. On May 25th, 1928, she was transferred to Glasgow Royal Infirmary for medical treatment.

Blood examinations: On May 25th there were 830,000 red blood cells per c.mm., the white blood cells numbered 2,600; haemoglobin 18 per cent.; colour index 1.0. On May 29th the red cells numbered 1,300,000 per c.mm.; haemoglobin 17 per cent. A film showed an ordinary secondary anaemia. On June 7th there were 1,270,000 red cells per c.mm.; haemoglobin 18 per cent. On June 18th the red cells numbered 1,710,000 per c.mm.; haemoglobin 26 per cent. A film showed ring-staining of red cells and poikilocytosis. No nucleated red cells were present.

On account of a persistent cough and an evening rise of temperature the suspicion of tuberculosis was raised, but a skiagram of the chest and a von Pirquet test proved negative. A detailed examination by the urologist was made, but beyond a well-marked cystitis, seen per cystoscope, no gross abnormality was detected in the urinary tract. On June 11th and 13th the patient had severe attacks of epistaxis. On the latter date a blood culture was made, but this was negative after ten days' incubation. Her general condition improved, and there was no further uterine bleeding. She was dismissed, much improved, on August 15th, the diagnosis being chronic nephritis. There was, further, no recurrence of uterine haemorrhage, but her general health deteriorated, and she died at home on November 13th, 1928.

In this case of a young woman, aged 27, no explanation of the single, very profuse uterine haemorrhage is apparent beyond the condition of chronic nephritis. Osler[5] states that haemorrhages, particularly epistaxis, are not infrequent in chronic interstitial nephritis. Berkeley[9] writes that haemorrhage from the uterus may occur in chronic renal disease, in which not only is the composition of the blood altered, but the blood pressure is raised and arterial degeneration is present. General blood-vascular diseases may affect the uterine vessels in the same manner as those of other organs. In elderly women they may be atheromatous, and Eden and Lockyer have, in one case, found definite sclerotic changes in the arteries in a uterus removed for uncontrollable bleeding. Certain diseases, such as chronic nephritis and general arterio-sclerosis, sometimes occur in connexion with chronic metritis.[10]

CASE VI.

This patient, aged 30 years, admitted on October 9th, 1929, complaining of profuse bleeding per vaginam of ten days' duration. Hitherto her menstrual periods had been regular but excessive, the flow lasting for about eight days. On examination she was found to be blanched, the mucous membranes being almost colourless. The uterus was slightly enlarged, but no other abnormality was detected. Her past health had been very good. She had been married for eight years and had no family.

Rest in bed and haematinics were prescribed; the haemorrhage ceased, and she was dismissed, much improved, on October 31st. On December 9th she was readmitted as an urgent case of uterine haemorrhage, bleeding having been present for fourteen days.

On examination she was found to be exsanguinated. The pulse was rapid and thready, and a systolic cardiac murmur was present. Despite measures for the arrest of haemorrhage, bleeding continued. An attempt to make a detailed blood examination failed, as sufficient blood—almost colourless as it was—could not be obtained by the usual method. Thirty-six hours after admission a blood transfusion was performed, but during the course of it the patient died.

This case of a young married woman is one from which a lesson is to be drawn—namely, the necessity for detailed general and blood examination in the absence of a local cause of profuse uterine haemorrhage. She was dismissed from hospital, apparently much improved after her first residence, only to return and die of a recurrent haemorrhage two months later. The actual cause of bleeding in this case was unknown, except that it was not due to any appreciable pelvic abnormality. One patient in the series of Linton, Marks, and Smith (loc. cit.) was moribund on admission, from excessive flowing of ten days' duration, and she died on the following day; no pathological basis for it is mentioned.

CASE VII.

This patient, a woman aged 49 years, was admitted to hospital on December 3rd, 1929, as an urgent case of uterine haemorrhage. The history of the illness was that in September, 1929, her menstrual period lasted for ten days; two months later bleeding recommenced and persisted for four weeks—that is, until admission. At no time had there been any pain. On examination she was found to be exsanguinated and the pulse feeble and rapid.

Prior to September, 1929, menstruation extended for four or five days, and recurred at irregular intervals of from four to seven weeks. She had been married for seventeen years and had four children. After her first confinement (twins), in 1913, she had very severe post-partum haemorrhage, and was confined to bed for six weeks. The second puerperium (in 1914) was also associated with post-partum haemorrhage, but not as severe as in the previous one. In the following year she had an ante-natal haemorrhage, and developed pneumonia and enteric fever during the puerperium. For many years she had a tendency to bleed unusually readily.

On the day of admission 1 c.cm. of haemoplastin was given; rectal salines with glucose and sodium bicarbonate were administered four-hourly. A blood transfusion (500 c.cm.) was performed. On December 7th a curette was introduced into the uterus, but no evidence of malignant disease or of other gross cause for haemorrhage could be found.

A blood count taken on December 6th showed: red blood cells 1,100,000 per c.mm., white cells 10,000; haemoglobin 28 per cent.; colour index 1.3; polymorphonuclear leucocytes (including transitional neutrophils) 86.5 per cent., eosinophils 1 per cent., mononuclear lymphocytes (including basophil myelocytes) 2.5 per cent., small lymphocytes 10 per cent.

She was transferred to a medical ward at the Victoria Infirmary on December 7th. On admission there she was described as being *in extremis*, and another blood transfusion (500 c.cm.) was given. She consumed twelve pints of water and two pounds of glucose in forty-eight hours.

A blood examination was repeated on December 10th, and showed: red cells 1,180,000 per c.mm., white cells 16,700; haemoglobin 32 per cent.; colour index 1.45. A film showed poikilocytosis, polychromatophilia, and polymorphonuclear leucocytosis. Another blood transfusion (500 c.cm.) was given on the following day, and a blood examination on December 12th showed: red cells 1,220,000 per c.mm., white cells 12,600; haemoglobin 32 per cent.; colour index 1.3. A film showed similar features as in the one made two days previously.

A swelling appeared in the right submaxillary region and increased in size, the cheeks became oedematous, and the tongue greatly swollen. Mechanical respiratory distress became severe. Slight haemorrhage per vaginam continued throughout. She died on December 15th, 1929.

Post-mortem examination revealed no macroscopic features of note. The liver and spleen were normal. A film from the bone marrow, however, showed the characteristic features associated with anaemia (pernicious) of the aplastic type.

There can be little doubt that the fatal uterine haemorrhage in this case was due to the constitutional disease, aplastic pernicious anaemia. A feature of interest was the history of post-partum and ante-partum haemorrhages at her confinements, some fifteen years previously.

Severe uterine haemorrhage in pernicious anaemia is rare. Linton, Marks, and Smith (loc. cit.) record a case of a patient who was treated with radium on account of fibroids, the presumed cause of her menorrhagia, but two years and eleven months later she died of "pernicious anaemia" (*State Records*).

Conclusions.

I have described seven cases of urgent uterine haemorrhage in which no local or pelvic cause was discoverable, and which were presumably of general or constitutional origin.

When bleeding is severe and the true diagnosis at an early stage is missed, the prognosis is grave; four of the above patients were dead within a month of admission to hospital, one within two months, and one (Case V) within six months.

Other factors than dysfunction or disease of uterus and ovaries are responsible for some cases of uterine bleeding. Cases occur in which it is to be attributed to a pathological condition of the blood.

The mechanism of haemorrhage in these cases is not clear, but it may depend on disordered calcium metabolism—for example, increased calcium output or low blood calcium.

In cases of severe uterine haemorrhage without obvious pelvic or local cause, a systemic investigation and a detailed blood examination (preferably by a haematologist) should be made at the earliest opportunity.

I am indebted to the surgeons of the Royal Samaritan Hospital for Women, Glasgow (Drs. Shannon, West, Gardner, and McIntyre), and to the medical superintendents of the Glasgow Royal and Victoria Infirmaries (Drs. Grant and McCall Smith respectively), for access to records and notes in some of these cases.

PRODUCTION OF PERNICIOUS ANAEMIA (BARTONELLA ANAEMIA) IN RATS BY DEFICIENT FEEDING.*

BY

LUCY WILLS, M.A.CANTAB., M.B., B.S.LOND.,

AND

MANECK M. MEHTA, M.A.BOMBAY, PH.D., D.SC.LOND.

(From the Nutritional Research Laboratories, I.R.F.A., Coonoor, South India.)

THE dietetic survey of various classes of women in Bombay suggested that the disease occurring in pregnant women known as "*pernicious anaemia of pregnancy*" was closely connected with a relative deficiency of vitamins A and C in their diet. In this connexion a series of experiments was carried out at Coonoor in which diets relatively deficient in these vitamins led to the production of a severe anaemia in intact albino rats, especially in the female animals; it was further shown to be a true "Bartonella anaemia." The term "Bartonella anaemia" is used to describe the well-known anaemia of rats which occurs after splenectomy in infected stock, and is associated with the appearance of Bartonella "organisms" in the red cells; it is used without prejudice as to the exact nature of these small bodies.

DIETETIC EXPERIMENTS.

The diets used had one common fault—a relative deficiency in vitamins A and C.

Series I.

These experiments have been reported before by McCarrison,[1] in his work on the production of urinary calculus by faulty feeding. In them two types of diet were used, the one based largely on oatmeal, and the other on atta (whole wheat flour). These diets contained no vitamin C and only a little vitamin A, the latter being obtained from the small quantity present in the grains used. Vitamin B was judged to be present in adequate amounts.

Cases of a severe, and frequently fatal, anaemia occurred among the rats fed on these diets: among those fed on the oatmeal diets there was a death rate from this disease of 13.8 per cent.; among those fed on the atta diet there was a death rate of 12.4 per cent. Milk added to the oatmeal diet appeared to afford the rats protection against this anaemia. The disease was much more frequent in females; out of a total of seven pregnant animals in one experiment five died of this anaemia.

The diagnosis of Bartonella anaemia was made on an examination of the blood slides. The characteristic appearances in the blood will be described in the account of the next series of experiments; in these the blood examination was much more complete.

Series II.

Six diets, two natural and four synthetic, were used in this series of experiments. The two natural ones were based on diets in common use among the hospital class in Bombay; one resembling that used by Mohammedan women and the other based on a diet used by Hindu women. Of the four synthetic diets the first was a basic one without vitamins A and C except such traces of vitamin A as might be found in the olive oil used (very little if any present, as the animals went downhill rapidly); the others were the same as the first with the addition of orange juice to the second, cod-liver oil to the third, and both orange juice and cod-liver oil to the fourth.

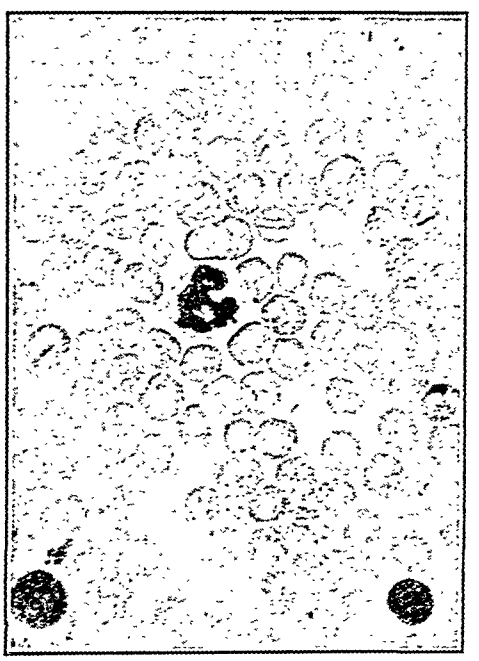

FIG. 1.—Blood from splenectomized anaemic rat showing "Bartonella organisms" in the red cells. (×1,000.)

Cases of Bartonella anaemia occurred spontaneously among the rats fed on the Mohammedan diet and among those fed on the basal synthetic diet. Pregnant animals living on the Hindu diet were, however, susceptible to inoculations of Bartonella-infected blood; in this respect they were unique, as we failed to produce an anaemia after inoculation either in well-fed rats, whether pregnant or not, or in pregnant rats when they were fed on the Hindu diet to which vitamins A and C were added in the form of cod-liver oil and tomato juice.

The amount of vitamin B and salts and also of fat varied in the different diets. The Mohammedan diet, on which the animals developed the anaemia most rapidly, was markedly deficient in vitamin B (poor growth from the beginning of the experiment) and salts, and at the same time had a high content of vitamin-A-free fat. The Hindu diet, on the other hand, had more vitamin B and a very low fat content. The synthetic diets had what has been shown to be an adequate amount of vitamin B and salts. The animals on complete synthetic diet grew well. The common factor in the diets which led to the production of the anaemia was, therefore, a relative deficiency of vitamins A and C, or very possibly some other dietetic fault associated with this deficiency.

*Summary of a paper appearing in the *Indian Journal of Medical Research*.

The anaemia was severe, as shown by the extreme pallor of all the organs and by the blood counts. Haemoglobinuria was common. The most striking post-mortem feature, apart from the general bloodlessness, was the fatty, mottled liver. This organ appeared to be enlarged; but when its weight was charted against body weight it was found that the organs obtained both from intact and from splenectomized rats fell within normal limits. In cases exhibiting haemoglobinuria the bladder was distended with dark-coloured urine and the kidneys were large and very dark. The bone marrow showed no macroscopic change.

The blood showed the typical picture of a macrocytic anaemia. The red cell count fell in certain cases from 10 to 1.35 million, and the haemoglobin from 13.2 to 4.9 grams per cent. This fall was associated with a marked degree of anisocytosis; the average diameter of the red cells was increased from 5.9 μ to 8.2 μ. As the anaemia progressed large numbers of normoblasts appeared in the blood stream. But the finding that clinched the diagnosis of Bartonella anaemia was the presence of the characteristic rod-like bodies in the red cells (Fig. 1).

Splenectomy Experiments.

In order to confirm the diagnosis arrived at in the previous experiments, and to show that all the stock and experimental animals were infected with Bartonella, and in addition to test various lines of treatment, a series of representative animals were splenectomized. Sixty-six animals were operated on by Colonel McCarrison. Of these one died of haemorrhage from the pancreas in the first twelve hours; the others survived the operation well. Post-operatively all the animals were fed on the stock diet with the addition of unlimited whole milk; 25 had no further treatment, 17 were treated with liver extract, 12 with fresh spleen, and 11 with vitamin A concentrate (radiostoleum). With a few exceptions all the animals developed the anaemia; liver, spleen, and vitamin A extract afforded no protection against the "infection" in splenectomized rats.

The clinical, pathological, and post-mortem appearances were identical in the splenectomized rats and in those developing the anaemia as a result of faulty feeding, save that the former had no spleens and their blood picture showed an enormous polymorphonuclear neutrophil leucocytosis and a much heavier incidence of red cells "infected" with Bartonella. The leucocytosis is probably a direct result of the splenectomy as it occurs immediately after the operation; but the reason for the number of "infected" red cells being so much greater, although the anaemia is no more severe, is not clear.

Inoculation and Cultural Experiments.

With the exception of the above-mentioned experiments with pregnant animals fed on a Hindu diet all attempts to produce anaemia by the inoculation of infected blood into intact animals were unsuccessful. We were also unable to confirm Ford's[2] work with young rats. All attempts to culture the "organism" failed.

Discussion.

The interest of these experiments lies in the fact that it has been possible by dietetic means alone to produce a severe Bartonella anaemia in intact animals, the anaemia being of the same order as that occurring after splenectomy in infected rats. The diets used have one common fault—a relative deficiency in vitamins A and C. There were many other experimental animals in close contact with those which developed the disease, but although all were infected, as shown by the splenectomy experiments, only those fed on diets with this dual deficiency developed the anaemia. It seems safe to conclude, therefore, that the factor that renders intact rats liable to this anaemia is a dietary one. The present series of experiments is not sufficiently conclusive to determine the exact nature of the deficiency; the results suggest that either a relative deficiency of vitamins A and C or of some other closely associated dietetic factor, perhaps a specific anti-anaemia one as found in liver, is most likely to be responsible. The presence of the characteristic "organism" in the red cells clinches the diagnosis of Bartonella anaemia.

It is suggested that the deficiency, whatever be its exact nature, may have some effect on the reticulo-endothelial system comparable to that of vitamin A deficiency on epithelial structures; and that it is by virtue of this action that the natural resistance of the intact rat is overcome, even as it is overcome in infected stock by removing a large bulk of this tissue—that is, the spleen. In view of the importance of the reticulo-endothelial system in the defence of the body against infections, particularly protozoal ones, the experiments reported here may not be without significance in connexion with the incidence of these diseases in India, where a large section of the population exists on diets having the faults described above.

Summary.

1. A severe anaemia has been produced in rats by feeding them on diets low in vitamins A and C.

2. The anaemia was more frequent and more severe in females than in males.

3. Blood examination revealed the presence of *Bartonella muris* in the red cells of the anaemic rats.

4. Splenectomy experiments showed that all the Coonoor rats were infected with Bartonella.

5. Liver, spleen, and vitamin A concentrate failed to protect the rats from this anaemia after splenectomy.

We wish to thank Colonel McCarrison for placing the material from his earlier experiments at our disposal, and for his generous help in this work.

TREATMENT OF ANAL FISSURE AND SPASM BY DIATHERMY.

BY

FRANK HOWITT, C.V.O., M.D., M.R.C.P.,

PHYSICIAN IN CHARGE, PHYSIO-THERAPEUTIC DEPARTMENT, PRINCE OF WALES'S GENERAL HOSPITAL.

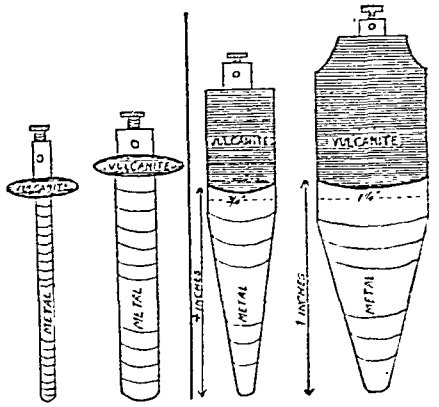
The use of high-frequency currents in the treatment of haemorrhoids and fissures and other painful and ulcerative conditions of the anus was first advocated and practised by Professor Doumer of Lille in 1897. Doumer introduced into the anus a conical metal electrode attached to the Oudin resonator of the original high-frequency apparatus. A detailed report of eight cases treated by Doumer's method was published by Seeuwen[1] in 1906.

The advent of the modern diathermy apparatus rendered possible a greater and more sustained production of local heat, and Bensaude and Meyer,[2] by employing this current, were able to improve upon Doumer's original technique. They published a report of 114 cases so treated with markedly beneficial results. They made use of a modification of Doumer's electrode in their more chronic cases, but in the very acute ones they did not attempt to penetrate the anal canal even with a fine electrode, confining themselves initially to a saline pad pressed against the orifice of the canal. The indifferent electrode was a pad placed upon the lumbar region. Finally J. H. Marchand[3] reviewed these various methods in the *Journal Médical Français* in 1929.

Our own experience of the treatment of certain ano-rectal cases by diathermy leaves no room for doubt that it is a curative agent of considerable value. Cumberbatch has drawn attention to the efficiency of this form of treatment, but it is remarkable that it has been so little employed in this country. The types of cases most suitable for its employment may be roughly subdivided under two headings—acute and chronic.

Acute Cases.

These include: (1) simple anal fissure and other ulcerations of the ano-rectal mucous membrane; (2) inflammatory and ulcerative conditions of the anus associated with haemorrhoids; (3) cases following operations on haemorrhoids and other operations in this area, in which the mucous membrane has not healed. Such cases are always attended with a considerable degree of spasm of the sphincter ani. The spasm cuts off the blood supply to the underlying mucous membrane, and the resultant tissue



anaemia prevents healing from taking place. The pain caused by the unhealed mucous membrane sets up a reflex spasm of the sphincter, and a vicious circle is thus produced.

Chronic Cases.

The late results of all these conditions are not uncommonly seen. Fissures and ulcers have healed over by scar tissue, resulting in fibrous bands and contractions. The lumen of the canal is partially occluded, rendering defaecation painful and difficult. Constipation is induced, and the attempt to pass a normal stool produces a fresh tear. In such cases one frequently finds on rectal examination areas of old scarring and contracture in one segment and a recent tear in another, attended with persistent spasm of the sphincter. If the fibrosis exceeds the ulceration the stools are malformed. The attention of the patient is often concentrated upon these disabilities, and a definite state of hypochondriasis may be set up. If the ulceration exceeds the fibrosis, pain and spasm predominate.

Technique.

The patient lies on his side in the Sims position. We use as the indifferent electrode the metal abdominal belt described by Cumberbatch[4] and Robinson in the treatment of cervicitis. All towels and instruments should be sterilized, and complete asepsis observed.

Electrodes used in acute cases. | Electrodes used in chronic cases.

In very acute cases it may be found necessary to begin the first treatment by applying a pad to the anal orifice, as recommended by Bensaude and Meyer, with the object of reducing the spasm, but we have never met a case in which it has not been possible to insert a fine electrode before the completion of the treatment. All electrodes should be warmed to a temperature of thermal indifference with the skin, and well lubricated with sterile vaseline before insertion. The very greatest care should be exercised in introducing the electrode. We begin with a metal rod of 3 mm. diameter and of uniform bore. The sphincter closes tightly upon it. The current is turned on and very gradually increased until a sensation of warmth is appreciated by the patient, but it should never exceed 300 milliamperes with this electrode, because in very acute cases the patient is sometimes unable to distinguish the sensation of heat from that of pain. (Normally this transition takes place at about 115° F.) In a few minutes the spasm begins to relax, and the patient often volunteers the remark that the instrument appears to be falling out. The electrode *should be held in situ* for ten minutes. During this period a painful reflex spasm of the anus may occur from time to time, but this will gradually decrease and finally disappear. It will now be possible to move the electrode up and down quite freely without producing further spasm. It is then removed very carefully, and another of slightly wider bore inserted and retained for a further ten minutes. Treatment in the early stages should be continued daily or even twice daily. At each treatment the initial electrode should be of slightly smaller bore than that selected at the end of the previous treatment. In this way it is usually found possible to increase on each successive application, until full dilatation is obtained. The relaxation of the sphincter induced by the diathermy current remains for a considerable time after treatment, and defaecation is rendered less painful. Regeneration of the mucous membrane is promoted over the ulcerated surface by the increase in blood supply, and the passive dilatation of the canal prevents the occurrence of fibrosis.

In chronic cases in which stenosis of the canal has taken place as the result of fibrous contraction, and which are often the late result of operations for the removal of haemorrhoids or of old ulceration in this area, active ulceration is not usually present, although attempts to pass a stool of normal consistency may produce recurrent tears in the adjacent mucous membrane. The patient is driven to the use of every kind of purgative, the passage of a stool of normal size and consistency in some cases being mechanically impossible.

In these cases it is usually found possible to insert a fine blunt electrode without difficulty. The method we adopted was suggested to us by Dr. A. F. Hurst, who had previously treated cases with success. It consists in the use of a much more intensive application of diathermy, with the object of rendering the whole area flaccid and malleable. The anal canal is then dilated manually. Recourse is had to the conical electrode of Doumer. These we had made of varying gradients according to the type of case to be treated, the position of the stricture, and the degree of dilatation required. In no case should the electrode exceed four inches in total length, in order to ensure that its tip should not impinge upon the roof of the pelvi-rectal flexure. It is graduated at intervals of 1/2 cm. in order to check the progress made at successive treatments. The electrode is pushed forward until slight pain or discomfort is experienced, and is left in this position for a few minutes, and then further inserted. This process is repeated at each operation. The amperemeter is not a good guide as to current, because the surface contact varies in individual cases, and this increases as further dilatation is obtained. More than 1,400 milliamperes can be given. At the end of each treatment, which lasts from twenty to thirty minutes, the forefinger is inserted, and later both forefingers, and the canal is gently but firmly stretched. It will be found that a much greater degree of dilatation can be produced after diathermy than is possible without such application, and the tendency to spasm is very considerably reduced. The dilatation produced has in most cases been permanent, and there has been no recurrence of fibrosis.

PROTEIN THERAPY IN INSANITY.

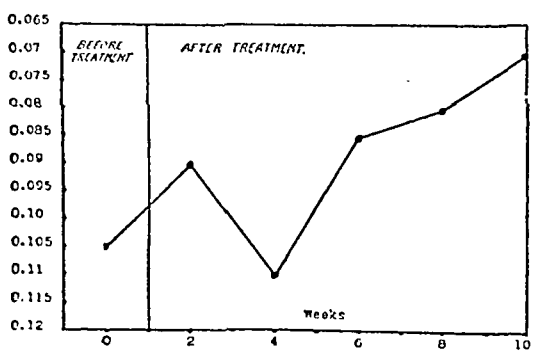
BY

JOHN R. BEITH ROBB, F.R.F.P.S.GLAS.,

SENIOR ASSISTANT PHYSICIAN, GARTLOCH HOSPITAL, GLASGOW.

DURING a recent outbreak of dysentery it was observed that the blood of patients who eventually died of the disease showed the highest estimation in agglutinative properties. Although these patients had a considerable amount of specific antibody, it would appear that for some unknown reason they were unable to utilize it against the infection. Since complement is considered necessary in a reaction of this nature, it might be reasonably assumed that the amount present had been insufficient, or at least not in proper proportion to the amount of antibody and antigen.

It has been demonstrated in our laboratory that in order to produce complete fixation of specific antigen and antibody in known quantity, the amount of complement required had to be, within limits, in proportion to the amount of antigen and antibody. The complete fixation did not take place if the quantity of complement was too great or too small. Whether this applies to reactions in



vivo it is difficult to say. Should this be the case, however, then it would seem that in order to get complete fixation of antigen in the body, complement will require to be present, within limits, in proportion to the quantity of antigen and antibody. In a given case of illness it is almost impossible to estimate the quantity of antigen, consequently the estimation of total complement presents obvious difficulties. As complement in the body is partly free and partly combined, estimates can only indicate the amount of free complement.

In "toxic confusional insanity" some cases after a short illness end fatally, while others presenting an almost similar clinical picture make a rapid recovery. Many clear up after months of confusion, while the more unfortunate victims develop permanent secondary organic changes in the brain. The duration and prognosis of the illness are in a great many cases a matter of speculation. Little or nothing is known of the toxins, their origin, or their antibodies, and consequently treatment tends to become non-specific. If the patient makes a rapid recovery it is reasonable to assume that he produced the necessary antibodies and complement to destroy the toxins. When he remains confused and physically exhausted for months, making no progress, it is possible that, as in the dysentery cases above mentioned, he is producing antibody but cannot make the balance in complement. The fact that confused and stuporose patients sometimes become clear mentally during an intercurrent illness may be due to the upsetting of the relative proportions of complement to antigen and antibody, thereby giving the antibody a temporary control over the antigen.

McIntosh[1] found that, apart from producing a slight diminution, the injection of vaccines had little influence on complement. McCully at this hospital, however, in some cases produced a fall, followed by a rise in free complement, by adminstering T.A.B. intravenously. Three asylum patients with very severe acne of several years' standing, resistive to all forms of treatment including vaccines, recovered only when they showed a rise in free complement.

Increase of Free Complement.

The following method appears to produce an increase of free complement in a considerable number of cases. Human serum when withdrawn and allowed to stand for a few days is alleged to become "anticomplemental," at least its presence in some way inhibits the action of the complement in fresh serum. On this hypothesis the "anticomplemental" serum is injected into the patient in the hope that any free complement in his blood will be absorbed, thereby stimulating a physiological increase of fresh complement—an analogy being the administration

Graph indicating complement based on figures from the table in cases which recovered from confusional insanity.

of an alkali to stimulate the production of HCl in the stomach. One cannot be dogmatic about the explanation of the reaction, but I find that the procedure can bring about an alteration in the value of free complement with beneficial results, especially in confusional states without secondary dementia. After injections of the serum, complemental estimates indicated an initial fall followed by a rise, the leucocytic cell count following the same curve. These results are shown in the accompanying graph. Injections given on alternate days produced better results than those given on consecutive days.

Technique of Treatment.

The technique is simple. About 90 c.cm. of blood are drawn into a test tube from the cubital vein. The test tube is rotated to prevent the clot from sticking to the side of the tube. The blood is put on ice; in twenty-four hours the serum is separated and centrifugalized; 2 c.cm. are retained for complement estimation and the remainder is put up in a sterilized serum bottle with a rubber cap. This is left on the ice for five days, 0.04 c.cm. of carbolic acid per 100 c.cm. of serum being added on the fourth day.

First Day of Treatment.—Two c.cm. of serum are given subcutaneously (abdominal wall), followed in one hour by 6 c.cm. The patient may complain of headache and slight shivering. He may become more restless and confused, and in about six hours the temperature usually drops to about 96.5°, the pulse rising to 100. A few hours later the pulse and temperature are again normal.

Third Day.—12 c.cm. of serum are administered subcutaneously. The patient is usually quieter, tends to sleep, and is more easily managed.

Fifth Day.—25 c.cm. of serum are administered

Sixth Day.—Blood is withdrawn for a second course of injections. Complement should be estimated in twenty-four hours.

Three or four courses of injections may be necessary before obtaining a rise in free complement. It is advisable to estimate complement before and after each course of injections.

The figures given in the accompanying table indicate the smallest amount of patient's serum which allows five doses of immune body completely to haemolize 1 c.cm of a 3 per cent. suspension of sheep's washed red blood corpuscles in a water-bath at 37° C. for an hour.

Results of Treatment.

After the first injections the condition of the skin and mouth becomes much cleaner, and the patient looks healthier. Although confusion persists, mental improvement is first noted in the fact that the patient is less restless, sleeps better, takes more food, and tends to be cleaner in his habits. Eventually the patient has short lucid intervals which gradually become longer. The improvement, which appears to have some relation to the increase in free complement, should take place in the course of a few weeks. I consider that by improving the patient's physical condition the treatment gives him a better chance of recovering from his confusion. A number of confused patients were treated in this way, the results being indicated in the table. It is possible that the "toxic" cases would have recovered if left alone, but they had all been in the observation wards before certification, and after admission to this hospital they continued to deteriorate both physically and mentally and to become dirty in their habits.

Other Methods of Producing Protein Shock.

Probably the treatment is a mild form of protein shock, the biochemistry of which is still obscure. My experience so far, however, has been that "toxic states" appear to improve with a rise in free complement.

In general paralysis, malaria inoculation, a dangerous and violent form of protein shock, is now past the experimental stage. It is generally accepted that varying degrees of remission can follow inoculation, but the underlying syphilis is unaffected to any great extent. Combination with antisyphilitic drugs is therefore imperative.[2] Bunker states that out of 2,460 cases treated with malaria 27 per cent. remitted, while in 542 cases treated with tryparsamide 35 per cent. remitted.[3] Fribourg-Blanc claims that with malaria alone 46 per cent. remitted, of whom 22 per cent. died later, while with malaria *plus* antisyphilitic drugs 66 per cent. remitted with a subsequent mortality of 6.7 per cent. The mortality in the first two months of malaria therapy is given by Meagher[4] as 40 per cent. McCully and I believe that any beneficial effects which follow malaria therapy are in part due to the auto-protein shock resulting from the enormous destruction of blood corpuscles which act as foreign protein. There are phases in the course of general paralysis during which it is almost impossible to tell whether the signs and symptoms are organic or toxic in origin. When remissions have been procured with protein shock the condition of the patient,

* A persistent blood Wassermann reaction 16+ was reduced to 12+, but reverted to 16+ with fall in complement.

I consider, has been more toxic than organic. The use of relapsing fever (*Spirochaeta duttoni*) is even more dangerous, as its action cannot be controlled. It may set up violent inflammatory processes in the meninges, with coagula in the cerebro-spinal fluid, recovery from which is questionable. Antityphoid or T.A.B. vaccines intravenously give results which are almost as satisfactory as those of malaria. The shock can be controlled, and institutional treatment is not absolutely necessary. The shock influences the leucocytic cell count and the complement estimate. But again, as in all protein therapy in general paralysis, antisyphilitic drugs must be used.

The effects of protein therapy in encephalitis lethargica are only transient. In epilepsy injections of proteins have given varying results. The pathogenesis of the disease is so obscure that it is difficult in many cases to determine whether the condition is psychical, toxic, or organic. Results so far, however, seem to indicate that states of stupor, confusion, and excitement may be ameliorated, but the disease as a whole is uninfluenced.

The same difficulties arise in dementia praecox. In the early untreated cases remissions from stupor and confusion take place, indicating that the psychosis at this stage is probably more toxic than organic. Blume treated 33 schizoid women with neosaprovitan B, a preparation containing living air bacilli, cocci, sarcinae, and dead *coli* vaccine. Of this, 0.001 to 0.003 c.cm. is administered intravenously every two to three days, gradually increasing to 1.5 c.cm. in a course of twelve to fifteen injections. The cases were treated on an average for three and a half months after the onset of the disease, with the following results: cured or improved 57 per cent., temporarily improved 7 per cent., and unaffected 36 per cent. Of 25 untreated cases, 40 per cent. were improved, 44 per cent. were unaffected, and 16 per cent. died.

Videla,[5] after using many forms of protein, considered that Witte's peptone gave the best results. A 5 per cent. solution is made in sterilized and filtered physiological salt solution. He discovered that the mode of administration gave varying results.

Intramuscular: Doses of 5 c.cm., 10 c.cm., 15 c.cm., and 20 c.cm. can be given into the gluteal muscles at intervals of 72 to 96 hours. The doses are modified according to the severity of the case.

Intravenous: Doses of 1 to 5 c.cm. give uncertain results.

Subcutaneous (abdominal wall): Used mostly in melancholia in doses not exceeding 5 c.cm.; 10 to 15 injections may be given. Anxiety was diminished in some cases.

Intradermal: This method was discontinued owing to the risk of sloughing and ulceration.

Within a short time of treatment the patient tends to become restful. There is some shivering, arterial hypotension, and rise in temperature. This is usually followed by sweating, bradycardia, and polyuria. The general reaction is over in twenty-four hours, leaving the patient feeling weak and with the desire to lie in bed. Contraindications are cardiac and hepatic diseases.

Over a period of five years Videla claims that out of 218 cases of insanity treated in this way 16 relapsed, 5 eventually recovering with further treatment; 44 are still undergoing treatment, 13 of whom are improving. The remainder were discharged "recovered." He considers that as a non-specific treatment peptone injections have given satisfactory results. He believes that the shock "modifies the colloidal equilibrium of the blood plasma."

Current literature gives little information about the influence of protein shock on complement, but I consider that it is a field which should be explored as the information obtained may be useful as a guide to the patient's reaction when undergoing this form of treatment.

I offer my thanks to Dr. A. M. Dryden, physician superintendent, for his courtesy in giving me permission to carry out the investigation discussed in the first part of this article, and also to Mr. Winkworth, our laboratory assistant.

DAMAGE TO THE SCIATIC NERVE FROM INTRAMUSCULAR ADMINISTRATION OF QUININE.

BY

A. G. BIGGAM, O.B.E., M.D., M.R.C.P.,
MAJOR R.A.M.C.(SECD.),
PROFESSOR OF CLINICAL MEDICINE, EGYPTIAN UNIVERSITY; DIRECTOR OF MEDICAL UNIT, KASR-EL-AINI HOSPITAL, CAIRO.

A FEW cases have been reported in which nerve lesions have resulted from the injection of quinine in the vicinity of nerve trunks. The following case, in which the lesion affected the sciatic nerve, illustrates the necessity of avoiding important nerve trunks in administering quinine intramuscularly.

The patient, a male aged 30 years, attended at the out-patient department complaining of pain and weakness in the right leg.

History.

He stated that about three months previously he had attacks of shivering and fever on alternate days, and a doctor, diagnosing

malaria, injected quinine (amount unknown) into his right buttock in the region of the gluteal fold. Immediately the injection was made the patient experienced a sharp, shooting pain running down the sciatic distribution as far as the foot of the same side; the pain lasted only for a second, and was immediately succeeded by a feeling of numbness and heaviness in the limb.

The remainder of the history was difficult to obtain accurately owing to the patient's dull mental condition, but he stated that during the seven days following the injection the affected limb remained free from pain but paralysed; this period of freedom from pain was succeeded by a period with marked pain and tenderness in the limb, especially below the knee, this condition persisting acutely for twenty-five days and then gradually subsiding. The exact distribution of the pain during that period is uncertain. The limb gradually began to regain some of its power, and by the time the patient attended the out-patient department it had recovered sufficiently to enable him to get about unaided. Apart from the above symptoms, his health had been good.

Condition on Admission.

On examination there was marked wasting and flabbiness and weakness of the flexor muscles of the thigh and of the calf muscles of the right lower limb. There was tenderness on pressure over the sciatic nerve below the region of the gluteal fold, this discomfort being most marked in the muscles of the calf. Pain in the sciatic nerve distribution was induced by flexion of the thigh on the abdomen and extension of the knee. Examination of the superficial sensations showed an area of anaesthesia on the outer side of the right leg, extending from midway between the knee and ankle down to and involving the outer border of the foot, all superficial sensations being lost in this region. Some blunting of sensation was detected outside this area of complete anaesthesia. Marked hyperaesthesia, especially to pin-prick, was found in the inner half of the sole of the foot. Deep sensations were normal.

The knee-jerks were present, equal and brisk on both sides; the ankle-jerk was present and brisk on the left side, but absent on the right side. The patient could now walk, but his right leg was still very weak, and he was unable to rise on his toes on the affected side. He was obviously suffering from the effect of the injection of quinine given either into, or in close proximity to, the sciatic nerve.

The irritative effect of quinine given subcutaneously or intramuscularly is well known, the subcutaneous route sometimes leading to obvious sloughing. The intramuscular injection also causes tissue damage and muscle fibre necrosis, but here the damage is deep-seated and so usually only detected on examination of the site of injection post mortem in fatal cases. The danger of tetanus following intramuscular quinine injection is one that must always be kept in mind, the necrosed tissues affording a favourable nidus for any organisms that may gain access along with the quinine.

Recently the occurrence of fixation abscesses at the site of intramuscular quinine hydrochloride injections has been reported by Giglioli[1] in a series of cases of paratyphoid C infections. Of 59 patients with paratyphoid C infection, to whom intramuscular quinine was given, 20 developed abscesses at the site of the injection, containing short and long Gram-negative rods, the organisms apparently gaining access through the blood stream.

In view of the local pain produced by intramuscular injections of quinine, and of the various complications that may possibly result from this method of administration, many authorities consider the intravenous route safer than the intramuscular, and now employ it as a routine in all cases with marked vomiting or with any other symptoms, the presence of which makes it necessary to get the patient rapidly under the influence of the drug. If precautions are taken to use not more than 0.5 gram at a time of a soluble preparation of quinine diluted in not less than 5 c.cm. of water, and to inject this very slowly intravenously, I have never found any ill effects resulting from this method of administration. The action of quinine given by this route is more rapid, and all danger of local ill effects is also thereby avoided.

A CASE OF NARCOLEPSY.

BY

STANLEY E. DENYER, C.M.G., M.D., F.R.C.S., M.R.C.P.,

CONSULTING PHYSICIAN, HULL ROYAL INFIRMARY.

ACCORDING to Gowers the term "narcolepsy" is best applied to a condition in which there is a tendency to fall into a sound sleep for a short time, usually for a few minutes, rarely for an hour or more. It is distinguished from trance by the brevity of the attacks of sleep, by their strong tendency to recur, and by the fact that the patient can be roused.

The patient in this case was a girl, aged 19, who was admitted into the Hull Royal Infirmary under my care. She gradually began to be sleepy when 16 years old. At night she went to sleep naturally, but would waken in two hours, and was afraid of being alone in the dark. She would scream out, being terrified, and then doze off, but would not get a proper sleep. Gradually, however, she became a little better, and slept more naturally, but lately she has grown worse. She now sleeps two to two and a half hours, awakening always in a fright, then dozing off into an unsatisfactory sleep.

She rises at 7 or 8 a.m., falls asleep at her breakfast and at all her meals, and sometimes between her meals. This happens every day. Even when talking to anyone she goes to sleep, loses consciousness, and falls against the table, remaining in this position for two or three minutes until she gradually recovers. When she has finished her meal she does some housework, but if she feels the sleepy feeling coming on she lies down. Two months ago she left her work on account of the sleepiness; she stopped work of her own accord, as she was a good worker, and her employer did not want to lose her.

During the attacks she never bites her tongue, never passes her urine or faeces unconsciously, and she has had no difficulty in eating or drinking. She has fallen a few times and knocked her head without wakening. She often dreams, but has no nightmares. No giddiness is present, but she is slightly deaf. After an attack she seems to be quite fresh and to have benefited from the short sleep. She appears to work up gradually to the next attack. From four to nine attacks may occur in a day. They last on an average from ten to fifteen minutes, but they are getting longer. Sometimes she turns quite pale during an attack. The number of attacks increases during her periods to about nine a day; also during the week before and the week after; they are longer at this time, but not more severe. Her periods are regular and normal, and last four or five days. She has had no illness except measles when a child.

Examination showed her to be of very good physique. The heart, lungs, abdomen, and urine are normal. Pubic hairs grow as high as the umbilicus. She is mentally intelligent but emotional. The knee-jerks are equally exaggerated; ankle-jerks are present. There is no ankle clonus, but rectus clonus is present on the left side. The pupils are equal, and react to light and accommodation; there is no nystagmus. Abdominal reflexes are present and normal; the plantar reflexes were not elicited. The cranial nerves are normal. There is no hypotonus, no Kernig, no inco-ordination, no anaesthesia or hyperaesthesia, and no flexibilitas cerea. A Wassermann test was negative.

An examination of the patient for worms was negative. Her periods were regular, but these seem to have affected the sleepiness to some extent. Her eyes were examined by an ophthalmic surgeon; her throat, nose, and ears by a throat surgeon; her teeth were good. An *x*-ray examination of the skull was made and revealed nothing abnormal.

The conditions in which sleepiness occurs are: (1) epilepsy, (2) trance, (3) catalepsy, (4) encephalitis lethargica, (5) sleeping sickness (trypanosomiasis), (6) narcolepsy, (7) katatonic form of dementia praecox.

Differential Diagnosis from the Above Conditions.

In epilepsy (petit mal) unconsciousness lasts only a few seconds, and is almost always followed by headache. A trance lasts for hours, days, or weeks; hysteroid phenomena occur and other manifestations of hysteria. From catalepsy her condition was distinguished by the absence of muscular rigidity. The chief characteristic of catalepsy is the maintenance for hours of some attitude that would very soon fatigue a normal person; the limbs remain as if petrified. In encephalitis lethargica there is diplopia, or a history of it, and very often a moral change, or Parkinsonism may follow, or rigidity and weakness. It was not sleeping sickness due to a trypanosome, because she had never been abroad, and there was no wasting, as is always found in the late periods of that disease. It is more difficult to distinguish her condition from the katatonic form of dementia praecox. During her stay in hospital she had an attack of a hysterical kind, which might be described as approaching a maniacal nature. It was probably nothing more than a hysterical attack; it is well known that in

organic nervous disease patients may, and frequently do, get such attacks.

The treatment on which most reliance was placed was caffeine citrate 10 grains, liq. strychninae 3 minims, and nitroglycerin 1 minim. Gowers quotes a case of his in which a girl had attacks commencing at the age of 16 and lasting till she was 22. They were almost identical with those in the present case, and were arrested by the same drugs. These had no effect in this case. Later she was also given thyroid gland (dried) 2 grains, hormotone 5 grains, three times a day, with no effect.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ANOMALOUS PETRO-SQUAMOUS VENOUS CANAL COMPLICATING MASTOID OPERATION.

A BOY, aged 5, was brought to me with acute mastoiditis supervening on chronic otitis media: the only unusual clinical feature was that the maximum swelling and tenderness were above and rather in front of the ear, the mastoid process itself appearing unaffected. This generally indicates a very cellular mastoid in which the root of the zygoma has become pneumatized, so that infection from the antrum can travel forward into the temporal fossa. An operation, however, revealed that the mastoid was diploetic, and practically acellular; and, as so often happens in such a condition, the dura of the middle fossa tended to come well down over the upper part of the antrum. The latter had been opened, and I was enlarging the opening upward, working (rather cautiously on account of the position of the dura) from within outwards with a hand gouge, when there was a sudden brisk effusion of venous blood. This was puzzling; I was too far forward to wound either sigmoid or superior petrosal sinus; and it is very improbable that the gouge used thus would penetrate a sinus wall, which slips away under it. I supposed that I had damaged a large dural vein. It was also inconvenient, to say the least, for the bleeding seemed to come exactly from the region of the aditus, which was only just exposed; and the packing necessary to control it interfered with proper exposure of the aditus and of the root of the zygoma. When the bleeding was controlled I found that a large vein or sinus, about 3 mm. in diameter, ran in a bony canal across the roof of the mastoid antrum, about 1 cm. deep, and parallel, to the surface of the squama, and above and somewhat superficial to the aditus. It was separated from the middle fossa by a complete thin plate of bone, but its inferior or antral wall may have been dehiscent.

In early foetal life the lateral sinus drains into the primitive jugular vein—which in the adult becomes the external jugular—through the post-condylic foramen, which pierces the root of the zygoma immediately in front of the bony external auditory meatus. Later the internal jugular grows up internal to the primitive, forms the jugular bulb and, after entering the skull, the sigmoid sinus, and thus provides the normal adult effluent of the lateral sinus; the post-condylic foramen then closes. Occasionally, however, the original primitive venous channel coexists with the normal adult arrangement; we then find a petro-squamous sinus grooving the inner aspect of the angle between petrous and squama, communicating anteriorly with the temporo-maxillary vein through a persistent post-condylic foramen, and posteriorly canalizing the superior margin of the petrous to enter the lateral sinus. The vein or sinus that gave me trouble appears to be a variant of this petro-squamous sinus, situated in the substance of the bone instead of grooving its inner surface.

The sinus and canal are interesting from three aspects: first, the condition might explain why in the case of an acellular zygoma the mastoid infection approached the surface anteriorly; secondly, it produces an anomaly very inconvenient to the operator, even when the possibility is known; thirdly, it must be somewhat rare; in the course of several hundred mastoid operations I have never encountered anything like it. Convalescence was uneventful.

E. WATSON-WILLIAMS, Ch.M.,
Surgeon in Charge, Ear, Nose, and Throat Department, Bristol Royal Infirmary.

DEATH FOLLOWING AN ALVEOLAR ABSCESS.

THE following details of an unusual sequel to alveolar abscess seem to deserve recording.

A healthy man, aged 25, had had no previous illness except indigestion six months previously, when he was advised to have dental treatment; this he did not do. On February 1st I was called to see him, and found an alveolar abscess in the left lower jaw. He had had very little sleep for some nights and looked ill, but he refused to have the tooth extracted under gas. Two days later I saw him again; the abscess having broken inside the mouth he felt much better.

On February 6th his wife reported that he was quite well, except for a slight headache. That same evening at 5 o'clock, while having tea, he said, "Oh, my head," and fell off his chair unconscious. When I saw him half an hour later he was unconscious, breathing stertorously, cyanosed, and sweating. The temperature was 102°; the pulse was irregular, the rate being about 120. He had bilateral external squint, the pupils were small and equal, and there was no reaction to light. There was marked rigidity of the neck, arms, and legs. He had passed both urine and faeces. He remained in this state until he died five hours later. No post-mortem examination was allowed.

My senior partner, Dr. J. C. Griffiths, also saw this man, and we are of the opinion that he had a blood-borne infection in the brain which caused an abscess to form; this eventually burst, resulting in acute septic meningitis. The fatal termination was very sudden, and emphasizes the fact that a prognosis must be guarded, even in cases of what are called "minor ailments."

Kidderminster. P. DIGBY GRIFFITHS, M.B., B.Ch.Camb.

RUPTURE OF THE HEART.

A FEW days ago a man, aged 65, dropped dead in the street. Inquiries from members of the family elicited the information that he had been complaining of pain in the chest and back, with aching in both arms, and numbness and tingling of the ring and little fingers of both hands, chiefly the right. These symptoms were not severe enough to cause him to seek medical assistance, and, apart from them, he enjoyed good health.

At the request of the coroner for East Lancashire, I made a post-mortem examination. The pericardium was found to be enormously distended, and, when opened, a large quantity of serum escaped, together with a large clot. On the posterior surface of the left ventricle there was a tear one inch in length. The aorta was normal, except for atheromatous deposits in the cusps of the aortic valve. The transverse branch of the left coronary artery was completely occluded by atheroma, almost two inches from its origin. Two inches beyond this point there was a patch in the posterior wall of the left ventricle, an inch in diameter and less than a quarter of an inch in thickness, in the base of which was the tear already referred to.

The case is interesting in view of the rarity of the condition and the absence of serious symptoms preceding death. My own interest in the case was enhanced by the fact that I reported a similar one in the *Journal* of July 16th, 1927 (p. 99).

Ramsbottom. C. W. CRAWSHAW, M.B., D.P.H.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

BORDER COUNTIES BRANCH.

RHEUMATIC DISEASES: CAUSATIVE FACTORS AND TREATMENT.

AT the annual general meeting of the Border Counties Branch of the British Medical Association, held on June 6th, Dr. MURRAY B. STEUART, the president, delivered his address from the chair, taking as his subject, "Rheumatic diseases: causative factors and treatment." He drew largely upon the discussions at the Bath conference on this subject in 1928 (*British Medical Journal*, i, p. 852), endeavouring to co-ordinate the various opinions with a view to arriving at a common denominator.

Dr. Steuart began with a word on the question of nomenclature, and after indicating the common confusion,

as shown by the various definitions given by recognized authorities, he mentioned with approval the classification put forward by the Ministry of Health, which had been adopted in many Continental countries, and which offered itself as a basis for the description and discussion of this wide range of allied diseases. The classification comprised three main groups—rheumatic fever and subacute rheumatism, non-articular manifestations, and chronic joint changes—and there were nine subdivisions.

Causation.

Turning to the question of rheumatism in the child, he quoted from Dr. Vining of Leeds University, who had spoken at the Bath conference on the pre-rheumatic child; from Dr. Dingwall Fordyce, who was in accord with Dr. Vining as to intestinal defect being a principal cause of rheumatism in the child; from Dr. Reginald Miller, who believed juvenile rheumatism to be an environmental disease, the environmental factors at work being centred to some extent around infection of the tonsils; and from Dr. Carey Coombs, who pinned his faith to the streptococcal origin of acute rheumatism, and was supported in that view by many other workers. Expert opinion during the last ten years had undergone a gradual and reluctant change, and even now it went no further than to admit that rheumatic infection in childhood must be included amongst the streptococcal diseases. The infection was caused, not by toxins alone, but by the streptococci themselves, which had been isolated from the exudate in cases of pericarditis, and occasionally, though not so commonly, from joint fluids, and had been cultivated directly from the blood stream as well. The answer to the question as to the portal by which these organisms entered the blood channels was as yet incomplete. That the tonsils were responsible was so probable that it might perhaps be treated as proved, though the evidence was indirect and inferential—namely, the fact that tonsillectomy was occasionally followed by an outbreak of rheumatic infection, and also that the streptococci of the tonsil were in the same category as those which were found normally in the human mouth and intestine. This latter evidence raised the question whether a portal of entrance might not be the intestine, a theory vigorously supported by Vining.

With regard to rheumatic disease in adults, Dr. Steuart again quoted various authorities, mostly those whose views were expressed at the Bath conference. According to Sir Humphry Rolleston rheumatic diseases might be streptococcal in origin, their clinical and structural differences being due to variation in the seed and inborn or acquired differences in the soil—namely, constitutional, endocrine, and other factors. One of the causes of chronic rheumatism much discussed was that of foci of infection. When the true cause could be discovered and efficiently treated, the result was undoubtedly dramatic, but Dr. Steuart thought the discovery frequently to be so difficult and illusory that treatment of the supposed cause often led to disappointment. Numbers of patients had had all their teeth extracted on the supposition that the septic absorption from them was the cause of their rheumatic state, and they had been grievously misled.

Speaking of the endocrine factors, Dr. Steuart said that the most obvious reason for bringing in these factors was that women at the climacteric not infrequently developed rheumatoid disease for the first time. Most of the exponents of the theory had confined their attention to the thyroid, though some had included the ovaries and other glands. Both hyper- and hypo-thyroidism might be associated with rheumatism; in short, the condition might be described as one of dysthyroidism, and the common factor was a lack of iodine, which might explain to some extent the reputed benefit produced by the administration of iodine in both rheumatoid conditions and Graves's disease. With regard to the ovaries, Cumberbatch and Robinson, in treating gonorrhoeal rheumatism by pelvic diathermy (which included the ovaries as well as the uterus), stimulated the ovarian function in such a way as to produce a return of menstruation after it had been in abeyance, and along with this there was a disappearance of arthritic pains and swelling and a return of full range of joint movement.

Treatment.

In speaking of treatment, Dr. Steuart confined himself to certain physical methods, the objective of which was the production of heat, either locally or generally. He thought that heat production in the treatment of these cases was justified by the habitual subnormal temperature of rheumatic subjects and their deficient capillary circulation. The application of heat by certain special means was capable of raising the temperature of the body, thus stimulating the circulation, increasing the metabolism, and encouraging the elimination of waste products, particularly lactic acid, which was one of the immediate causes of rheumatism and its allied diseases. He mentioned one case in which he had carried out Wilde's pyretic treatment of rheumatism—a treatment whereby pyrexia and sweating were encouraged. The case was that of a lad, aged 19, whose illness began subacutely with lumbago and some pain also in the sciatic nerve. He was put on salicylates for a few days, when he suddenly developed a typical attack of acute rheumatism, with a temperature of 101° F. His hands became swollen and sodden-looking, very painful, and incapable of movement, and the ankles were also affected. The administration of salicylates was stopped, and for an hour each day sweating was encouraged by the application of hot-water bottles and blankets (for want of special apparatus). Within four days the temperature had dropped to 99.4°, and the swelling of the hands had practically gone. In two more days the hands were normal, and the pain in the ankles had become very slight. The lad returned to work ten days afterwards, without cardiac lesion, and had been well since. In the method as used by Wilde a metal cover was employed, this being placed over the patient as he lay in bed. The cover had condensers inside, and steam was admitted to these condensers by a couple of pipes attached to a boiler at the foot of the bed. The escape of vapour was arranged by means of small holes in the condenser. The patient, enveloped in a sheet, lay on the bed in the moist-heated atmosphere for about twenty minutes or half an hour, and afterwards had a needle bath or spray or was quickly sponged down.

Another physical method for the treatment of rheumatic affections was diathermy, either by general or local application, and here again Dr. Steuart gave some account of successful cases in his experience. One case was in a woman, aged 22, who complained of rheumatic pains in hands and knees, and a sensation of coldness throughout the body. After four treatments on the condenser couch there was marked reduction of pain in all the affected joints, and a return of a feeling of warmth. After twelve treatments she had no pain at all, and had ceased to feel the cold. In this case he had combined ultra-violet treatment by mercury vapour with diathermy, but he attributed the improvement mainly to the latter. Ultra-violet radiation sometimes gave very good results in muscular rheumatism, but it was not so certain as diathermy. It was useful as an adjunct to other treatment in the way of improvement to the general health, but was disappointing in its results in the treatment of rheumatic diseases—other than muscular rheumatism—when used alone.

Dr. Steuart's general conclusion was that in the present state of knowledge there was no definite *causa causans* of rheumatic diseases, but that there were numerous contributory conditions, acting separately or in varied combinations, which were favourable to their incidence and development. These included improper environment, deficient diet, intestinal defect, endocrine imbalance, septic foci, and certain streptococci, either as normally present but in a non-resistant host, or abnormally virulent in a normally resistant host. As to treatment, again there was no royal road to complete and invariable success. When, however, some form of the disease had been more or less established, improvement or cure might be attained by combating toxic conditions by complete removal, or by treatment with antitoxins (using the term in the broadest sense), or by the use of measures, especially heat and diathermy, to assist Nature to reassert her resisting and eliminative powers.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF LARYNGOLOGY: SUMMER MEETING.

THE summer meeting of the Section of Laryngology of the Royal Society of Medicine was held on June 20th, under the chairmanship of Dr. DAN MCKENZIE. The morning session was devoted to a number of short papers and discussions, and the afternoon to a clinical meeting.

Foreign Bodies in Air and Food Passages.

Dr. D. A. CROW read a paper entitled "Thirty foreign bodies removed from the air and food passages." In the first case of the kind he ever handled, he said, he introduced a steel hook to remove a jagged half tooth-plate from the post-cricoid space in the oesophagus; the hook stuck, with unhappy results. He never afterwards attempted to use the laryngoscope until he had studied Chevalier Jackson's methods in Philadelphia, but since then he had never been unsuccessful in a case involving a foreign body. Coins impacted below the crico-pharyngeal bend were easy to remove if the case was treated in good time, if there had been no blundering attempts at removal, and if the operator bore in mind the tendency of coins to hide beneath the bend. Oesophagoscopy was in most cases quite a quick procedure. A general anaesthetic had been used in most of his cases; it was not impossible to use a local anaesthetic, but he preferred to avoid the psychological trauma this procedure involved. Among the cases was one in which *x* rays had failed to reveal two aluminium wires, and another in which a young child had inhaled part of a safety pin, but had had no symptoms, the vigilance of the general practitioner preventing a dangerous delay. In two cases dental plates had been swallowed during sea bathing. Laryngologists should implore dental surgeons to take far greater precautions to prevent teeth from slipping down the throat. Extractions should never be performed in a hurry, and a large gauze swab should always be placed behind the site of operation. On a tooth going down the throat, the dentist did not keep faith with the patient unless he at once procured radioscopic and bronchoscopic examination. In one case where the dentist had acted promptly, the crown of a molar was recovered from deep in the left lower bronchus with Jackson's side-grasping forceps, after bronchoscopy. While precise methods were available, rough or blind methods had little to recommend them, and it was for laryngologists to show that their technique rested on a scientific basis.

The PRESIDENT said that if the foreign body was large or had been *in situ* for some considerable time, or if signs of rupture of the oesophagus were present, the external operation should be employed. The deeper planes of the neck should not be opened more than was absolutely necessary, particularly towards the lower end of the neck and the mediastinum.

Mr. T. B. LAYTON defended the use of the "coin-catcher," saying that tragedies were caused, not by its use, but by its abuse. He thought also that if local anaesthesia were properly given, psychological trauma should not occur. Failures were sometimes brought about through a foreign body in the oesophagus setting up respiratory symptoms. He declared the use of the "coin-catcher" to be no more harmful than that of the endoscope, and it was a thing which should be taught to every student, so that when practising in some remote place he could deal with foreign bodies himself. Such bodies were sometimes caught in the last inch of the oesophagus, where they were very difficult to detect with the endoscope.

Dr. J. S. FRASER could not understand anybody preferring the "coin-catcher" to the endoscope; it was so much easier to remove coins when they could be seen. Mr. E. M. WOODMAN described the "coin-catcher" as a barbaric instrument, which in half the cases pushed the foreign body into the stomach. Mr. H. A. KISCH, on the other hand, said that much trouble in the war would have been avoided if students had been taught to use the "coin-catcher." Every case should have an anaesthetic, and the "coin-catcher" could be used with great precision and delicacy on an anaesthetized patient. Dr. DOUGLAS GUTHRIE spoke of the applicability of the external operation to foreign bodies in the air passages. Mr. M. VLASTO described a case in which he had dealt with an obstinate fish-bone successfully by pushing it into the stomach, and he suggested that similar cases might be fairly common. Sir JAMES DUNDAS-GRANT said that the "coin-catcher" had given long and useful service before the days of the endoscope, and was not by any means superseded. Mr. THACKER-NEVILLE feared lest students should use the "coin-catcher" on miscellaneous bodies such as bones. The endoscopists needed every opportunity of practising the use of the endoscope. No student of Professor Jackson could hear Mr. Layton "with anything but fierce rage in his heart." As for anaesthetics, most patients with foreign bodies were healthy and needed no anaesthetic beyond half a grain of morphine and a little cocaine paste on the epiglottis and the pyriform fossae.

Mr. HERBERT TILLEY said that his hospital's "coin-catcher" was in the museum, and he considered that the student should not be taught its use. In this country there was always a trained endoscopist within reach, even in remote districts, and a coin might remain *in situ* for forty-eight hours without much danger. Junior endoscopists often missed a coin in the oesophagus through not flexing the head sufficiently as soon as the constriction was passed, so that the tube overrode the coin. For local anaesthesia he recommended a swab of gauze soaked in 10 to 15 per cent. cocaine, and left for 10 or 15 minutes in each pyriform fossa. Professor Jackson had used this method practically always on adults, and where necessary on children. The speaker described how, when a tooth-plate had been retained in the stomach for six weeks, he had fed the patient for two days with strips of butter-muslin; she had then passed the foreign body wrapped up in the cloth. He also recounted a case in which, in spite of cellulitis and profuse suppuration, it had not been necessary to operate externally.

Mr. E. WATSON-WILLIAMS consigned both the "coin-catcher" and the probang to the museum. In the classical statistics, all the fatal foreign-body cases had been due to unsuccessful attempts at removal with these instruments. It was most important to have an *x*-ray examination immediately before endoscopy, and not to rely on one taken some hours previously. Dr. RITCHIE ROGER corroborated Mr. Vlasto's suggestion that a foreign body could sometimes with advantage be pushed into the stomach. He had dealt with a tooth-plate in this way. Dr. CROW, in reply, made a plea for the use of elegant methods.

Congenital Stenosis of Oesophagus Associated with Hiatal Hernia.

Dr. A. BROWN KELLY, in a short paper on this subject, said that persistent vomiting or regurgitation might be of oesophageal origin, and he went on to describe four cases in which oesophageal stenosis was associated with hernia of the lower end of the oesophagus and part of the stomach into the thoracic cavity: these had occurred in young children. He also referred to Akerlund's work on hiatal hernias. Mr. E. WATSON-WILLIAMS expressed gratitude for the light this paper threw on a case which had perplexed him; the diagnosis had been oesophageal carcinoma, and the constriction, halfway down the oesophagus, opened under a general anaesthetic, had disclosed the gastric mucosa. Dr. KELLY said the condition might be simulated by diverticulum of the oesophagus just above the diaphragm.

Diathermy of the Faucial Tonsil.

Dr. DAN MCKENZIE, in a paper giving details of gradual diathermy of the faucial tonsil, said that, although he preferred to remove tonsils by operation, owing to the speed of that procedure, diathermy was safe in ordinary hands, and of great use in the growing class of persons who refused operation. The whole tonsil or any part could be removed. He preferred to stop at the capsule; it was possible to leave a perfectly smooth fossa without any tonsillar tissue, keeping intact the anterior pillar and plica semilunaris. Symptoms—generally speaking, rheumatic—were relieved after the first or second application, and patients often wished to discontinue treatment at that stage. He always, however, removed the whole tonsil when the patient allowed him to do so. He employed the pointed

Benson electrode to prevent coagulation beyond the point of immediate application. The first coagulation should occur at the supratonsillar fossa, where most of the bacterial absorption probably took place. Difficulty began when the tonsil was reduced to the level of the pillars, for their removal caused much more pain. He always applied the electrodes with the pillar retracted, and, when he came near it, used the needle. The hard, firm feel of the capsule was unmistakable. The extension down towards the tongue could be dealt with afterwards. Diathermy might be given once a week at the beginning, but less often later; an interval should be allowed to let the reaction subside so that the tissue to be excised could be more clearly distinguished. The treatment need not be painful if the coagulated area were restricted and the pillars were left alone. Extensive or deep diathermy might induce a secondary haemorrhage during the separation of the slough, and for this reason the patient should not go out of the control of the operator. In reply to discussion Dr. McKENZIE said that he used surface anaesthesia and injected novocain. Separation of the anterior pillar was not necessary, nor was it necessary to carry the destruction through the pillar or the fibrous capsule, which did not harbour bacteria. Mr. H. BELL TAWSE said that diathermy might have as painful after-effects as section, but that it was more useful for patients who could not take an anaesthetic.

Granulomata of the Larynx.

Mr. E. WATSON-WILLIAMS described a number of cases of granulomata of the larynx caused by mustard or other irritant gas. After some years of painless hoarseness, symptoms of laryngeal obstruction were manifested, sometimes with aphonia. The neoplasm was composed entirely of granulation tissue, with a squamous epithelial covering; it was non-malignant. Sir STCLAIR THOMSON remarked on the rarity of these growths, and suggested their origin from submucous haemorrhage.

Avertin in Laryngology.

Mr. W. S. THACKER NEVILLE brought forward the subject of avertin as a basal narcotic in surgery. This drug, he said, was administered per rectum in doses of aqueous solution, according to body weight, 0.1 gram per kilo, and was absorbed with great rapidity. The only contraindications were kidney disease, low blood pressure, and gross sepsis from empyema. It was non-toxic, and could be given to children with great advantage. A local anaesthetic was usually given as well, for avertin was a basal narcotic, not an anaesthetic. So little ether was required that the after-effects were over before the patient recovered from the avertin. The blood pressure fell considerably, and lobeline and ephedrin were given after the operation. In nasal operations avertin allowed ether to be given instead of chloroform, and adrenaline could therefore be given with perfect safety.

Sir STCLAIR THOMSON thought that the paper might have been delivered with the object of warning laryngologists off avertin. He wondered how much of the effect was really due to the small quantities of miscellaneous anaesthetics which were given at the same time. Dr. LESLIE POWELL said that avertin was quite apt to cause death from respiratory failure unless the patient was carefully watched. Mr. THACKER NEVILLE, in reply, admitted that he preferred morphine and scopolamine and block anaesthesia. Avertin was useful, however, in intranasal work on children, and had a good psychological effect.

Cases and Specimens.

At the clinical session Mr. NORMAN PATTERSON showed a case of deformity of pharynx after an attempt at removal of the tonsils; Mr. WALTER HOWARTH, a case of carcinoma of oesophagus treated by lateral thoracotomy and radium (progressive improvement in swallowing after nine months); Mr. J. F. O'MALLEY, slides illustrating a case of endothelioma of tonsil treated by radium, followed by recurrence in abdomen, and death; Mr. E. A. PETERS, a section from a case of haemoptysis due to cryptal ulceration of tonsils, and also a section of papilloma removed from the left aryteno-epiglottic fold; and Mr. BELL TAWSE, a case of growth on larynx, attributed by the patient to "gassing" during the war.

PUERPERAL INFECTION BY THE PATHOGENIC ANAEROBIC BACTERIA.

AT a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on June 20th, with Mr. EARDLEY HOLLAND in the chair, Mr. A. J. WRIGLEY spoke on puerperal infection, with special reference to cases caused by anaerobic bacteria.

Mr. Wrigley said he hoped to publish papers on this subject in the future. Between the years 1922 and 1927 death from puerperal infection had occurred in 16 cases at St. Thomas's Hospital, and of these 6 had been cases of generalized gas gangrene. This number might represent an unusually high percentage, or the condition might be commoner than was generally supposed. He proposed to devote his paper to cases of infection due to the *Bacillus acrogenes capsulatus*. This organism, which had been isolated from soil, fish, milk, the bile, urine, mouth, and skin, was probably normally present in the faeces; but there was no evidence that it occurred in the upper part of the vagina or the cervix, or that any allied organisms were found there.

Specimens of lochia had been obtained from 50 cases, the technique employed being as follows: A sterile Fergusson's speculum was introduced into the vagina and the cervix exposed. A blunt, curved pipette, fitted with a rubber teat, was introduced into the cervix to a distance of about 1 inch, and 1/2 to 1 c.cm. of lochial material was withdrawn by means of the teat. This material was then expelled into a sterile test tube and cultured aerobically and anaerobically. In 50 patients from whom specimens were taken at the beginning of labour the *B. acrogenes capsulatus* was not found. In specimens from 100 cases, taken on the second, sixth, and, in some cases, ninth day of the puerperium, following a normal pregnancy and delivery, the bacillus was also absent. This led to the conclusion that the bacillus was not present before or after a normal labour, with the corollary that the organism must be introduced from without. This might occur by infection from the skin of the anal region during manipulation. A group of abnormal labours, 69 in number, was therefore investigated. In 13 of these cases the bacillus was present; the foetus had died *in utero* and, in some, gross manipulation had been necessary. At this point it was convenient to enumerate the conditions necessary to produce infection by the bacillus. First, there must be introduction from without, so that infection was liable to occur in cases requiring much manipulation. Secondly, the organism required suitable material for its culture *in utero*, and dead tissues, as supplied by a dead foetus, were particularly suitable. Thirdly, this material must remain in the uterus sufficiently long for the organism to multiply; hence infection was more likely to occur in cases where a dead foetus was retained for some hours or days. Finally, infection was more likely to occur if the maternal tissues had been damaged by manipulation. The lowering of maternal resistance and the virulence of the organism of course played a part in determining infection.

In 4 of his 13 cases, said Mr. Wrigley, the foetus had been dead *in utero* for some hours and considerable interference had been necessary. In all these the infection had been severe and the foetal and placental tissues were heavily infected. In 4 more cases, though the child was dead *in utero*, the damage caused by manipulation was thought to be slight. The bacillus was found in the lochia, however, for several days after labour, and associated with symptoms of puerperal infection. In 1 case the patient was eclamptic and a dead foetus was retained for five days; the bacillus was found in the macerated foetus and in the placenta on delivery, and also in the maternal blood stream immediately after death, which occurred shortly afterwards. In the remaining 4 cases, although the dead foetuses had been retained for periods varying from one to five days, bougies were used for induction, and there was no injury to maternal tissues; the bacillus was found in the placentae and the lochia of all 4 cases for several days, yet there were no symptoms of infection. It was impossible to predict beforehand what form infection by the bacillus might take in a given

patient, but some of the fatal cases attributed to shock, and possibly some of those ascribed to eclampsia, might be due to this organism. The possibility of infection might, and should, be suspected before the onset of symptoms if there had been gross interference or injury to maternal tissues, with a dead foetus *in utero*. The lochia should be examined early for the bacillus, and it should be identified by cultural reactions and animal inoculation. Treatment included prophylaxis by better midwifery, and early administration of antitoxic serum in large doses in all cases where the conditions for the development of this infection were fulfilled. The German advocates of hysterectomy were not justified in seeking such an extreme form of treatment. The lecturer concluded by stressing the danger of leaving a dead child in the uterus, and of performing any but the gentlest manipulations during its removal.

Dr. IVENS-KNOWLES described a case which had fulfilled nearly all the conditions mentioned by Mr. Wrigley, and in which recovery had occurred after the early administration of serum. Dr. J. WYATT said that among 100 cases he had helped to investigate the *B. aerogenes capsulatus* had not been found.

Dr. COLEBROOK said that there had been no deaths in Queen Charlotte's Hospital from this organism during the past two years. He suggested that, since it was found in the late war that an acidosis was essential for the growth of this bacillus in the blood, its rapid propagation in the presence of a dead foetus was due to the acidity of the dead tissues. He asked whether bicarbonate had been used to combat acidosis in cases of puerperal infection due to this organism.

In replying, Mr. WRIGLEY said that the reason the organism was not usually found was because either the patient was dead or else the organism was present in a state which was comparatively harmless. He had not used bicarbonate in the treatment of these cases.

Cases and Specimens.

Mr. H. K. GRIFFITHS recorded a case of lithopaedion, and a case of pregnancy in one horn of a bicornuate uterus. Mr. EARDLEY HOLLAND described a case of secondary melanotic sarcoma of the placenta with transmission to the foetus. He also showed with Mr. BREWS six specimens from an interesting case of fibromyoma of the uterus. Dr. J. BAMFORTH described three cases: the first, of carcinosarcoma of the uterus in a woman of 59; the second, of carcinoma supervening on a hyperplastic condition of the endometrium; and the third, of an endometrium of the abdominal wall following Caesarean section. Dr. IVENS-KNOWLES recorded a case of recurrent melanotic sarcoma of the clitoris with an unusually long history. Mr. RIVETT showed a uterus removed for intractable bleeding in a woman who had been treated with radium, and a cervical fibroid removed from a woman weighing 19 st.

ATYPICAL MENINGITIS.

AT a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on May 23rd, with the president, Dr. R. J. ROWLETTE, in the chair, a discussion was held on meningitis.

Dr. R. H. MICKS in a communication on atypical meningitis, related that during last year he had seen three cases of meningitis which had presented the following unusual symptoms: (1) a cerebro-spinal fluid which was turbid with polymorphonuclears; (2) the absence of organisms as tested both by direct film examination and by culture on standard laboratory media; (3) a negative Boveri reaction; and (4) an atypical course in that two out of the three patients recovered, and the third showed a very striking and well-maintained improvement until sudden death with a normal temperature. Dr. Micks referred to the fact that a mild recoverable meningitis was undoubtedly more common now than was once believed. Encephalomyelitis and associated meningitis of various types had increased in frequency of late, especially the type associated with vaccinia and measles, while there had been sporadic cases which were not associated with exanthems and were not apparently similar in course or post-mortem appearance to encephalitis lethargica. This was exemplified by the six cases described a little over a year ago by Russell Brain and others. But in all these examples of mild meningitis the cell count was usually low, and the predominating cell was the lymphocyte. A marked polymorph increase is apparently very rare in a meningitis which is not due to recognizable bacteria. For this reason he had thought these three cases worth recording as something distinctly removed from a lymphocytic meningitis or a "meningismus." Two further points of interest in connexion with the diagnosis and treatment of meningitis were touched upon: the great diagnostic value of Boveri's reaction properly carried out in the case of a clear or nearly clear cerebro-spinal fluid, and, secondly, the very marked polymorph leucocytosis which might follow the intrathecal injection of a foreign protein. This rather alarming phenomenon was not sufficiently known; indeed, the author had only been able to find one reference to it in medical literature.

Dr. V. M. SYNGE then read a paper on a case of meningitis associated with mumps.

A boy, aged 9, first complained of severe headache and vomiting on May 4th. The temperature was 104° and the pulse 156; he was delirious and semi-conscious. There was incontinence of urine, the neck was stiff, and there was a slight doubtful Kernig's sign. The pupils were equal and reacted to light, the knee-jerks were brisk, especially the left, and the right parotid was swollen. A lumbar puncture yielded a clear fluid under slightly increased tension; the globulin was increased, but sugar was absent and the Boveri reaction was negative. It was sterile on culture and no tubercle bacilli were found; the cell count was 360 per c.mm. (lymphocytes). The patient gradually improved, and left hospital on May 21st perfectly well.

Dr. Synge remarked that the enlarged parotid, the character of the cerebro-spinal fluid, and the rapid recovery left no doubt as to the diagnosis of mumps meningitis. Roux had stated that meningitis occurred in 1 per cent. of cases of mumps; Dopter had given 9.8 as the percentage of cases of mumps which showed meningeal symptoms, but he did not regard all these cases as being true meningitis. In Dublin meningeal complications certainly did not reach these figures.

The PRESIDENT said that Dr. Micks seemed to have touched the kernel of the puzzle in regard to a number of diseases in which the organism which gave rise to meningitis was unknown; he thought that some such infection probably accounted for Dr. Micks's first two cases. The second case might have been caused by some organism of the influenza class, and the subsequent cardiac condition might have taken its origin from that organism. He mentioned a case of urticaria which he had treated some years ago and which showed symptoms of meningitis; he gave sodium salicylate and the patient recovered perfectly. No lumbar puncture had been performed and no such thorough examinations made as would be made at present.

Dr. J. O'CONNOR mentioned the case of a baby 10 months old, who had been vaccinated on May 3rd, and who had become ill seven days later, when he was cross, very restless, and had vomited. Next day the baby was quiet and apathetic, and on admission to hospital resembled a case of tetanus. Lumbar puncture was performed; the fluid removed under tension was perfectly clear. The Boveri reaction was positive. Following lumbar puncture, the tetany spasms had completely disappeared, but next night further spasms occurred, and there was some rigidity of the neck. When Dr. O'Connor had tried to obtain Kernig's sign, the whole musculature of the child's body was thrown into action. A further lumbar puncture was performed, and again Boveri's reaction was positive. Lumbar puncture had been employed three times subsequently, and on the day of the meeting a ventricular puncture had been made through the fontanelle, perfectly clear fluid being removed under tension. At first it was thought that the case might be one of encephalitis following vaccination, but the vaccination had not taken, as there had been no reaction at all. The child was afebrile and no focus of infection could be found.

Dr. CYRIL MURPHY mentioned the possibility of the infection in some cases similar to those described by Dr. Micks coming from the antrum, and producing

inflammation of the dura and a slight Boveri reaction. He referred to a case which he had recently seen in which this had occurred, the patient ultimately making a good recovery. He thought that too much reliance should not be placed on the Boveri reaction. Dr. A. HALPENNY said she had found that cases in which the cerebro-spinal fluid was clear and contained lymphocytes and polymorphonuclear cells, and in which an immediate positive Boveri reaction was obtained, were invariably tuberculous. Dr. G. E. NESBITT described the case of a woman who, after severe headache and vomiting, had become very dazed and had very indefinite symptoms. A lumbar puncture gave vent to turbid fluid, and anti-meningococcal serum was then injected. No organism was found in the fluid. Lumbar puncture was repeated on the following day, and more serum was injected. After three days a few meningococci were found with great difficulty. The patient made a complete recovery. Dr. Nesbitt thought it was possible to have meningococcal infections in which the organisms were so few that it was impossible to find them.

Dr. J. LAIT mentioned a case of tetanus which had been admitted to hospital with definite trismus. Lumbar puncture was performed; the fluid was quite clear, but there was a slight increase in the cell content. Serum was injected, and the following day lumbar puncture was repeated, 10 c.cm. of turbid fluid being removed. More serum was injected, and the fluid on examination proved to be full of pus cells. The patient's condition improved, and in two days the fluid was sterile. This case, he thought, brought out the fact that an increase in polynuclear cells followed the injection of serum. The patient made a complete recovery. Dr. A. R. PARSONS thought lumbar puncture would greatly enlarge the physician's conception of meningitis. He noticed that Dr. Micks had used a large amount of antitoxin empirically, which seemed a rather rash proceeding. He personally always had the fluid examined first to see if the meningococcus were present before he injected antitoxin. Dr. MICKS replied that in all his cases there had been clearly marked symptoms of meningitis, and the fluid had come out quite turbid. He did not regard any of his cases as cases of meningococcal meningitis. He thought it was necessary to inject meningococcal antiserum before receiving the report on the fluid whenever turbid cerebro-spinal fluid was found on account of the well-known difficulty in finding meningococci in some cases. If the infection was not meningococcal no harm was done, provided that care was taken to avoid protein shock in a sensitive patient.

Spirochaetal Jaundice.

Dr. G. E. NESBITT described a case of spirochaetal jaundice.

A man, aged 22, had been sent to hospital last November as a case of "acute abdomen." Three days previously, when working in the fields, he felt violent pain between his shoulder-blades; in the afternoon it became so severe that he had to stop working, and two days later he came to hospital. He looked very toxic, and there was a definite icteric touch in the skin. His tongue was very furred, the temperature was normal, and the pulse 100. He vomited practically without ceasing from the time of his admission. The urine contained albumin and there was a slight reduction of Benedict's solution. The case was at first thought to be one of either acute pancreatitis, *B. typhosus* fever, spirochaetosis icterohaemorrhagica, or trichinosis. The second day after admission his condition was much the same, and the vomiting persisted, he complained of severe thirst and very severe pain in his legs. A blood film showed eosinophilia; the blood culture was negative. Next day jaundice was very marked, but he was still vomiting and very thirsty; he passed no urine, and a crop of red spots developed on his shoulders. Next day there was bad hiccup, and Fisher's solution was injected. On the following day he was still passing no urine and complained of great abdominal pain, much like the pains in his legs; it was then thought that he must be suffering from some acute abdominal condition. Next morning he passed about 2 c.cm. of urine, greenish in colour, but containing no spirochaetes. The abdomen was rather distended and tympanitic, but soft. Pituitrin brought about immediate relief from the abdominal pain. At 1 o'clock he became very weak and said he could not breathe, and at 1.45 got a similar attack and died. The liver and kidneys were large and smooth; the mucous membrane looked as if some strong acid was dissolving it away. All the organs were intensely bile-stained, but histologically showed very little damage considering the toxic condition of the patient clinically.

Dr. Nesbitt said that spirochaetal jaundice was originally described by Dr. Wilde in 1886. From the literature, however, it appeared that the same disease had been reported many years before his time by numerous authors, the first being Dr. Lavy in 1849. Until 1914 nothing more was known about the condition than the clinical features, but in that year a number of Japanese authors described the discovery of a spirochaete which was found in the liver of a guinea-pig which had been inoculated with the serum of a patient who was infected with Wilde's disease. The speaker referred at length to the work by the late Dr. Adrian Stokes with Ryle and Tytler, which established the nature of the infection in the cases which occurred in Flanders during the war.

Dr. T. T. O'FARRELL said he had examined specimens from the lungs, liver, pancreas, spleen, intestine, and a gland from the stomach in this case. He found nothing in the pancreas, but there was an organism in the spleen; he had failed to find organisms anywhere else, except in the kidney. He was quite convinced that they were spirochaetes, but it was impossible to say whether they were leptospira and whether the spirochaetes were the causal organisms. Dr. J. LAIT said he had examined specimens from this case and had not found any spirochaetes. He thought it possible, however, that spirochaetes might have been present, but was confident that there were no leptospira. Dr. W. H. ASHMORE mentioned the possibility of the case being one of metallic poisoning, probably arsenic poisoning, and asked if the organs had been examined for arsenic. Dr. J. O'CONNOR recalled a reference in the *Medical Annual* to cases similar to the one described by Dr. Nesbitt. In one case (described by Dr. De La Verne) a man fell into a ditch; a few days later well-marked jaundice and epistaxis with complete cessation of urine developed. In this case it was proved that the man had not swallowed any virus. Another case was a man whose finger had been bitten; the bite was followed by a whitlow, and jaundice developed. He mentioned an instance where a guinea-pig was bitten by a rat and jaundice ensued.

Dr. NESBITT, replying, said he had thought of arsenical poisoning, but no evidence of arsenic had been found in the organs examined. He thought the organs would have shown more damage histologically than they did if it had been a case of arsenic poisoning. Patients with spirochaetal jaundice were usually reported to suffer from diarrhoea, but his patient had obstinate constipation.

PSYCHOSES IN GENERAL PRACTICE.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society, held on June 5th, with the president, Dr. W. BARRINGTON PROWSE, in the chair, Dr. HELEN BOYLE read a paper on the milder forms of manic-depressive insanity and cyclothymia in general practice.

Dr. Boyle said that the term manic-depressive was part of Kraepelin's classification, and embraced, according to this author, a variety of conditions from acute mania to marked alteration of mood in the sane. She made a plea for several subdivisions under the heading manic-depressive, and called attention to the association between some manic-depressive states and thyroid disturbances—hyperthyroidism, hypothyroidism, and possibly dysthyroidism, and also a group associated with hyperpiesis, arteriosclerosis, morbid intestinal stasis, and kidney trouble. Real progress, she suggested, could only be assured in the treatment of these cases by close co-operation between general practitioners (who saw and treated all the early cases) on the one hand, and those specially interested in neuro-psychiatry on the other. Kraepelin had written as follows: "Manic-depressive insanity includes on the one hand the whole domain of so-called periodic and circular insanity, on the other hand simple mania, the greater part of the morbid states termed melancholia, and also a not inconsiderable number of cases of amentia. Lastly, we include here certain slight and slightest colourings of mood, some of them periodic, some continuously morbid,

which on the one hand are to be regarded as the rudiment of more severe disorders, on the other hand pass over without sharp boundary into the domain of personal predisposition." People liable to marked variations of mood, said the lecturer, were familiar to all, and most people had at times suffered from, and at times benefited by, the feverish energy, optimism, and determination to put things through of the cyclothymic. They were, in moderation, invaluable to the community. In their euphoric stages, short of insanity, they were sublimely self-confident, and devoid of self-criticism and inhibitions, and by that temper which could feel no difficulties, fine feats could be achieved. Some were eminently worth-while people. Cyclothymia, which signified a nervous or mental illness with a cyclic tendency, was a term applied to mild manic-depressive states in patients who were not insane and very possibly would never become so. Few would object to being called cyclothymic, while many objected to manic-depressive as a description of their condition. A number of authors, continued the lecturer, had observed the similarity between the hyper- and hypo-thyroidic illness and manic-depressive states, and it was noteworthy that in some of the latter there was a history of enlargement of the thyroid during adolescence, sometimes accompanied by cyclothymic tendencies. It would be of great value if practitioners would take note of this condition in schools or private practice and confirm or disprove the observation that it was a forerunner of cyclothymia in adult life. The treatment of the adolescent with thyroid enlargement would have to be modified, for it could hardly be doubted that the youngster should be set free from competitive work or play of all kinds, and the strain and anxiety that accompanied them. The group of manic-depressive states associated with hyperpiesis which might show themselves in early adult life had one clear indication for treatment. The blood pressure, even when considerable, should only be reduced with great care, and the treatment should be accompanied by steam baths, colon douches, and other eliminative measures. The high pressure was required for efficient excretion, and unless this was secured by other means an attack of insanity supervened. In these patients a systolic pressure of 185 to 190 millimetres of mercury was usually the lowest limit which was safe. These patients in later life showed confusion and disorientation in their attacks. Even in these patients, if the blood pressure rose and elimination was successful, the attacks might clear up in twenty-four hours.

BOHLER'S TREATMENT OF FRACTURED FOREARM.

At a clinical meeting of the Devon and Exeter Medico-Chirurgical Society, held on May 29th, with Dr. C. VINCENT SMITH in the chair, Mr. R. WAYLAND SMITH showed a boy, aged 11, with a recent fracture of the right forearm, to demonstrate Bohler's method. In this instance, the radiogram taken before the fracture was "put up" showed marked angulation inwards of the radius at the site of the fracture, and a greenstick fracture of the ulna. Bohler's method was undertaken to improve the position, three days after the fracture. The result, as shown by a second radiogram, was excellent as regards the position of the fragments. Mr. Wayland Smith, who had had the advantage of learning the technique at first hand when on the Continent, said that his method made for a revolution in the treatment of fractures, although the United Kingdom had so far been slow in adopting what had become almost universal outside. He then gave a brief account of the technique. The patient, lying upon a table, had the thumb and three fingers of the injured arm covered with gauze and collodion to afford a non-slip hold for the operator. Then, with the arm suspended and fixed, counter-extension was obtained by grasping the hand. At the same time the bones were manipulated into position. When position was obtained, plaster was put on next the skin—no fabric intervening—from the knuckles to the bend of the elbow anteriorly, and the middle of the arm at the back. Gooch splints were then applied, and, finally, more plaster. Movements were encouraged from the moment the plaster had set. The lad in question had his arm put up on a Thursday, and was using a hoe and rake on the following Monday; the result, as estimated at the meeting fourteen days later, appeared to be excellent.

Reviews.

RENAL DISEASE.

VOLUME xvii of the large French textbook on medicine[1] published by Masson is a complete treatise on renal disease, dealing with the subject from every aspect—physiological, pathological, clinical, and therapeutic—and including within its scope diseases that come within the province of both physician and surgeon. It is written by WIDAL, LEMIERRE, and PASTEUR VALLERY-RADOT, and we are informed in the preface that Widal had carefully revised every chapter during the last few months of his life. The volume may thus be taken to represent the final opinions of this great French physician, whose lifelong work on the problems of renal disease is known in every country.

Considered simply as a statement of the views of Widal and his school, the large section on the different forms of nephritis is obviously important, and will amply repay study. Only a few points from this section can be selected for mention. It is interesting to find Widal, in a short chapter of four pages on "war nephritis," insisting on the fact that cases of this disorder differed neither in their symptoms nor in their evolution and pathology from the acute nephritis met with in ordinary civil practice. In the chapter on tests of renal function the majority of tests commonly employed in this country are referred to, a notable exception being the MacLean urea concentration test. The importance of the urea concentration in the urine is, however, adequately discussed. Four full pages are given to a study of "Ambard's constant," an estimation which must seldom be carried out in this country nowadays.—The greatest emphasis is laid on the estimation of the blood urea, and Mosenthal's test is also given due prominence.

The short chapter entitled "L'ancienne urémie" raises questions of the utmost importance and interest. Widal, while admitting at once that the essential etiology of uraemia is obscure, states that he has worked for twenty years to put some order into the chaos surrounding this problem. The chapter begins with the ordinary divisions of uraemia into: (1) cerebral (including such symptoms as fits, coma, amaurosis, delirium); (2) respiratory (including dyspnoea and Cheyne-Stokes respiration); and (3) gastro-intestinal (including such symptoms as vomiting, diarrhoea, and intestinal ulceration). "Petite urémie" is distinguished from the grave and violent "grande urémie," and a division into "urémie lente" and "urémie aigue" is also made. But Widal claims that these various divisions, though useful clinically, lead to nothing; and some functional classification of the different types of uraemia is essential for prognosis and treatment. In this textbook the division is therefore made into the types of uraemia associated with nitrogen retention (azotémie), chloride retention, and arterial hypertension, and it is emphasized that uraemia may be very different in all its aspects in cases which can be placed in one or other of these three categories. The progressive and fatal coma of cases with nitrogen retention contrasts greatly with the less dangerous uraemic fits of other forms of nephritis in which chloride retention and oedema are the chief features. The coma in cases with nitrogen retention is preceded by a period, often of considerable duration, in which the only symptoms are fatigue, languor, loss of appetite, and often subnormal temperature. These are to be regarded as the cardinal clinical signs of nitrogen retention. In cases of high blood pressure the clinical features are the same, with the one added feature of hypertension. In cases with chloride retention premonitory symptoms are often absent altogether, and the prognosis of a uraemic attack is altogether much more favourable. The conclusion is emphasized that it is only by close investigation of the category into which the individual case of nephritis fits—nitrogen retention, chloride retention, or high blood pressure—that any reasoned prognosis or accurate treatment is possible in uraemia.

[1] *Nouveau Traité de Médecine*, Fascicule xvii: *Pathologie des Reins*. Par Fernand Widal, A. Lemierre, et Pasteur Vallery-Radot. Paris: Masson et Cie. 1929. (6½ x 10, pp. 1024; 100 figures, 3 plates. 125 fr.)

This textbook must be regarded as the most complete account of all forms of renal disease, ranging from nephritis to tumours, at present available. It has all the merits of clear French exposition, and all the peculiarities dependent on the isolated position which French medicine chooses to occupy. It is well worth reading, since in the study of renal disease no one can neglect the work of Widal and his school.

JOHN OF GADDESDEN'S "ROSA ANGLICA."

THE name of John of Gaddesden is still familiar, for he is mentioned by his contemporary Chaucer, and one of his books, no doubt "clothed in black and red," hung at the bed's head of the Doctour of Physicke. The *Rosa Anglica*[2] was written about 1314, and was for long a standard work of mediaeval practice, though it contains but little that is original. The work appeared repeatedly in manuscript in the fifteenth, and was printed at least four times in the sixteenth, century. It was never rendered into English as a whole, but portions of it were translated by the late Dr. H. P. Cholmeley in his scholarly thesis for the M.D. degree in 1912. Miss WINIFRED WULFF now supplies a larger portion from a translation from the Latin into Irish.

We are accustomed to think of Irish literature as having had a glorious past, followed by complete eclipse, but the researches of the Irish Texts Society, working on somewhat similar lines to the Early English Text Society, show this to be untrue, and we welcome Miss Wulff's contribution, which appears as the twenty-fifth volume issued by the society. Miss Wulff, in a painstaking and illuminating introduction, mentions fourteen Latin manuscripts of the *Rosa Anglica* and six translations from Latin into Irish. She says of these translations that the language is Early Modern, and that, apart from the technical terms, it would be intelligible to any good "Irish speaker" of the present day. It is evident, therefore, that there were people in Ireland in the fifteenth century who preferred to read a medical author in the vernacular rather than in Latin. There was a similar class in England about the same time, and it would be interesting to find out for whom the translations were made—clearly not for Churchmen, who read Latin as easily as their native tongue. In England it may have been due to the fact that an abortive attempt was made in 1423 to improve the standard of medical knowledge by forming a College of Medicine; the Irish have always been, and still are, greater readers than the English, as is shown by the bookshops in Galway and Cork, which would do credit to towns of much larger size in this country. The translations may, on the other hand, be a mere prelude to that great flood of literature opened up by the translators of the Tudor period a hundred years later. But, whatever the reason, the translations into Irish exist, and Miss Wulff says that they are accurate and show how the Irish language can be put to technical uses. On the whole they are literal, and reproduce the charm and quaintness of the original, so that they read pleasantly, and are clear and to the point. It bears out, she says, "Stanley O'Grady's contention that the mediaeval Irish were, when they gave their minds to it, excellent translators, and could solve the problem of how to render closely from a strange tongue without distorting the idiom of their own."

Miss Wulff has done her editorial work excellently, has provided a useful vocabulary, a list of the medical works quoted in the text, and a bibliography. She has perhaps somewhat underrated the position of the surgeons contemporary with John of Gaddesden. Whatever may have been the case in Dublin, in London the surgeon was not necessarily associated with the barber. Before the union of the Barbers' and Surgeons' Companies in 1540 the Fellowship of Surgeons was a well-recognized body co-opting its own members, practising surgery only, taking no apprentices, and not concerning itself with teaching. Master John Arderne was a member of the fraternity, and as he mentions a few words of Irish it would be interesting to know whether Miss Wulff has seen any Irish translation of his works, which were largely circulated in England but were never printed in full.

[2] *Rosa Anglica* (seu Rosa Medicinae). Johannis Anglici An early modern Irish translation of a version of [illegible] book of John of Gaddesden. Edited, with introduction, glossary, and English version, by Winifred Wulff, M.A. Irish Texts Society, vol. xxv. London: Simpkin Marshall, Ltd. 1929. (6 × 9, pp. lix + 434; 1 plate. 25s.)

INSOMNIA.

IN a volume entitled *Insomnia: An Outline for the Practitioner*,[3] Dr. H. CRICHTON-MILLER has clearly made it his aim to deal with this subject from the practical standpoint. The theories and mechanisms of sleep are adequately discussed, but emphasis is placed throughout on the clinical and therapeutic problems which the disturbances of sleep present. The medical practitioner will certainly find in this book much useful advice as to the methods of dealing with his patients who complain of insufficient sleep. Treatment is considered from both the medicinal and psycho-therapeutic standpoints, and, incidentally, the author makes out a good case for the utilization of psychotherapy in general practice. The book concludes with a number of illustrative cases which serve as problems in diagnosis and therapy, as comparable as may be to the problems that confront the practitioner when he has to deal with patients suffering from insomnia.

Insomnia: How to Combat It,[4] by Dr. JOSEPH COLLINS, is a useful addition to a Popular Health Series. In an easy and readable style the author gives the general reader an account of the causes, nature, and functions of sleep, and makes a number of suggestions which should be helpful to those who are sleeping badly.

POPULATION PROBLEMS.

DR. WARREN THOMPSON'S book, *Danger Spots in World Population*,[5] makes no specific appeal to medical readers, but it will be read by medical men, as by other educated minorities, with painful interest. Dr. Thompson's thesis is, briefly, this: It is a truism that most of the greater wars of the past have been due to pressure of population. A nation or tribe outgrows its own resources, it sees a less prolific nation in political control of natural resources which the latter is unable to utilize fully, and takes what it needs by force. But the same provocation is afforded to-day. Certain nations—for instance, Japan and Italy—have populations far beyond the resources of their proper political sovereignties. Other nations—the British Commonwealth and France are cited—control politically territories that their natural-born citizens have not effectively colonized, and, indeed—partly for reasons of climate, partly owing to industrial specialization—cannot colonize. Sooner or later, unless some more rational expedient can be devised, the "swarming" nations will dispossess the others by force of arms of what those others are incapable of using to the best advantage. A better expedient would be peaceful agreement, and, to that end, a candid and exhaustive statement of the facts and the examination of such statements by an international body would be requisite. In this book the author provides some data and examines seriatim the population problems of the whole world. His estimate of the position in our country is pessimistic. "It appears, then," he writes,

"that Great Britain, with all its vast resources, has, in many respects, the most difficult population problem of all the over-populated parts of the world. If the Japanese and the Italians were to be given suitable lands, they could care for their numbers without undue hardship until such time as birth control will result in a slowly increasing or even a stationary population. For these peoples are less specialized in their work and mode of life, and are yet adaptable to a variety of environments. There seems to be no clear way out of the present situation for Great Britain. Birth control is rapidly spreading to the entire population—the birth rate is now only sixteen or seventeen—and it may soon fall to the point where there will be no natural increase or even a natural decrease, but it will certainly be some time before

[4] *Insomnia: How to Combat It.* By Joseph Collins, M.D. Appleton's Popular Health Series. New York and London: D. Appleton and Co. 1930. (Cr. 8vo, pp. vi + 131. 5s. net.)

[5] *Danger Spots in World Population.* By Warren S. Thompson, Ph.D. New York and London: A. A. Knopf. 1929. (5½ × 8¼, pp. xi + 343 + x; 1 map. 12s. 6d.)

a natural decrease will roll up a deficit of five millions or more, which appears to be the surplus population to-day. The disposal of this surplus, consisting of the present army of unemployed and their dependants, as well as many of those in receipt of poor relief, is a problem that seems to us to defy any satisfactory solution."

It would not be hard to criticize details in Dr. Thompson's statements; to object that at some point his statistical basis is doubtful, at another point he has neglected such and such economic possibilities, and so forth. Again, it is certain that no readers—least of all, perhaps, those who imagine themselves to be most sophisticated—will really form a judgement of the issues upon wholly intellectual grounds. Anybody who has soaked his mind in Burke—and most Englishmen who take an intelligent interest in political evolution have soaked their minds in Burke—feels instinctively that the future of a nation cannot be foretold, for it will not be determined, by ratiocination. The future *may* be less gloomy than conscious reason would allow. Still, even such a reader will commend Dr. Thompson's undertaking. His book is pessimistic in the best sense of the word. He is not trying to make our flesh creep, but telling us what he thinks are reasonable deductions from what seem to be well-ascertained facts.

PROBLEMS OF MODERN THERAPEUTICS.

THOUGH "Therapy and Therapeutics: A Warning to Doctors, Clinicians, and Pharmacologists"[6] is but a small book, its author, Professor BOAS of Berlin, manages in it to discuss most of the problems of modern therapeutics, including in his survey such subjects as medical patents, quacks, polypharmacy, and valuable and valueless therapeutic publications. He is, as the title suggests, dissatisfied with the present state of therapeutics, which, in his view, is cumbered with relics of mediaeval superstitions that must be cleared away if the subject is to be established as an exact science. He opens with the famous statement made by Virchow more than half a century ago: "Therapeutics must seek the aid of pathological physiology to raise itself above the empirical practice of clinicians if it is ever to become a science, which at present it is not."

The author devotes some attention to the difficulties attending any endeavour to obtain exact and adequately controlled evidence about the value of therapeutic methods. It is very difficult, he points out, for manufacturers to get adequate clinical tests of a new drug even when laboratory experiments indicate that it is likely to be of real value. Clinicians of reputation are unwilling to organize tests with suitable controls, though they have at their disposal the clinical material that would enable them to do so. The result is that the drug is hawked round till finally it falls into the hands of certain practitioners who are notorious for the inevitability with which they obtain 100 per cent. successes with every new drug they examine. With a few publications from such sources the manufacturers are able to start a propaganda campaign, and therapeutics becomes cumbered with a new drug, which is probably no better and no worse than a dozen of its predecessors. Professor Boas feels that there is a need for some arrangement by which new drugs could be submitted to adequate and impartial tests.

NOTES ON BOOKS.

THE May number of the *Annals of Medical History*[7] contains three sketches of remarkable men—two French and one a Scotsman. Dr. B. B. Beeson of Chicago writes of J. N. Corvisart, whose portrait appears on the cover. Corvisart's diagnosis was sometimes almost miraculous, and of him it is told that on seeing a picture he exclaimed, "If the painter was exact the original of this portrait died of heart disease"; and this proved to be correct, as was also his disapproval of Napoleon's marriage with Marie Louise, who was so much his junior. Of Alphonse François Marie Guérin (1816–1895), whose portrait forms the frontispiece, Dr. J. C. Wilson of Philadelphia says that beyond the borders of his own country his reputation as a clinician has never properly been recognized. George Fordyce was famous for his Gargantuan daily meal and for the following episode, which Dr. W. B. Howell tells: when called in his days of poverty to a rich woman and finding himself intoxicated he reproachfully murmured "Drunk, by God," a description which, fortunately for the Scot, the patient knew applied to herself, and accordingly bought his silence for a hundred pounds. Fordyce is also mentioned in Sir Humphry Rolleston's MacAlister Lecture on medical friendships, clubs, and societies. Dr. E. H. Hume of New York writes on medicine, ancient and modern, in China, and Dr. R. H. Shryock on the public relations of the medical profession in Great Britain and the United States, an article which, as it covers the period from 1600 to 1870, is rightly the longest in this number; it naturally contains a good deal about homœopathy and other medical cults. This number is noteworthy for the information provided about the incunabula in three American libraries—those of the New York Academy of Medicine which possesses 117, the Washington University School of Medicine, and the University of Rochester. Dr. F. R. Packard in an editorial refers to other American libraries rich in incunabula, and reviews Dr. Peyton Rous's Linacre Lecture on "The modern dance of death," delivered last year in Cambridge.

The British Red Cross Society has produced a second edition of its *Hygiene and Sanitation Manual*, No. 4,[8] first published in 1914, and reprinted on several occasions. Under the editorship of Lieut.-Colonel G. S. PARKINSON the changed outlook on military hygiene and sanitation resulting from the great war has been embodied in this little volume. A large amount of information is set forth clearly and concisely, and over seventy illustrations, from the *Manual of Military Sanitation* and other sources, assist in explaining technical descriptions in the text. In one case the illustration seems to be more correct than the text. In describing the lay-out of a camp site, it is stated that "the 'sanitary area' is placed to the windward side of the camp." The illustration gives the correct position to leeward.

Economic Housekeeping,[9] by J. S. BAINBRIDGE, is a small treatise on food values and marketing which attempts to translate "the language of the laboratory into the dialect of the household." It begins with a discussion on the food requirements of the body, elementary and occasionally rather sweeping in its implications. The examination of household budgets and the marketing advice about meat, vegetables, fish, game, and fruit afford useful hints for novices, though it seems doubtful if it is necessary to inform any purchaser not to acquire meat that has an unpleasant smell or vegetables that are "limp and soft."

PREPARATIONS AND APPLIANCES.

CAROTENE PELLETS.

THE preparation "carotene" put on the market by British Drug Houses, Ltd. (Graham Street, City Road, N.1) is very welcome, for it will facilitate clinical tests of the interesting results that have been recently recorded with this substance. Euler, Euler and Hellström[1] in 1928 showed that crystalline carotene produced effects similar to those of vitamin A; their results were confirmed in this country. Recently Green and Mellanby[2] found that pure carotene conferred complete immunity in growing rats against the development of spontaneous infection. Mellanby[3] had previously shown that vitamin A was an important anti-infective agent, and, in particular, had reported results which indicated that a rich supply of vitamin A might exercise a definitely beneficial effect in puerperal septicæmia. In view of this experimental work, which suggests that carotene may prove to be a protective agent of exceptional importance, extensive clinical tests are obviously desirable. The preparation is in the form of pellets for oral administration, and each pellet contains 2 mg. of pure crystalline carotene. Green and Mellanby found that about one-fiftieth of a milligram of carotene daily was sufficient to protect rats against infection.

"SOMNOSAL."

"Somnosal" (H. R. Napp Ltd.) is a combination of α-brom-iso-valerianyl urea with dimethyl-amido-phenyldimethyl-iso-pyrazolon. The makers claim that it is a reliable sedative, that its toxicity is negligible, that it is non-cumulative, and free from tendency to tolerance or habit formation. It therefore appears to possess all the virtues usually claimed for new hypnotics.

ROYAL SANITARY INSTITUTE.

ANNUAL CONGRESS AT MARGATE.

THE Royal Sanitary Institute has been holding its forty-first congress at Margate during the past week. After the inaugural address by the president of the congress, Lord CORNWALLIS, who, in welcoming the gathering of delegates to Kent, reviewed the health problems of the county and the way in which they were being solved, the congress divided itself into seven sections and seven conferences, each "conference" consisting of representatives of a particular line of public service, in which discussions went on in some cases simultaneously.

Imperial Aspects of Preventive Medicine.

Sir ANDREW BALFOUR, presiding over the Section of Preventive Medicine, delivered an address on "Some imperial responsibilities in hygiene," which was in certain respects an echo of his recent Hastings Lecture before the British Medical Association. He declared that as a nation we could look with considerable satisfaction on the way in which, of late years, through local administrations, the medical and surgical problems presented by British possessions in the Tropics had been approached. One result of the recognition of imperial responsibilities in hygiene was that writers of books on health subjects found that they could no longer neglect the maladies of the Tropics, and those aspects of tropical pathology which had a bearing on the public health. It was refreshing to see, Sir Andrew Balfour declared, how the work on tropical hygiene had reacted on home hygiene. Teachers and expositors of hygiene found that they must widen their outlook, and view, not this little island only, but the vast Empire of which it was the heart and head.

Professor W. W. JAMESON, in a paper on "The education of health personnel," gave some account of the instruction given at the London School of Hygiene and Tropical Medicine in its new era. In speaking of the desirability that some general experience of practice should be obtained before this specialized course of study was entered upon, he mentioned that of the 33 students at present sitting at the London School for the D.P.H., 25 had qualified more than two years before their admission to the course, 15 had held residential appointments in hospital, 9 had done general practice, and 9 had held appointments abroad. Dr. ARTHUR E. HORN, consulting physician to the Colonial Office, spoke on the tropical training of sanitary personnel, and sketched the duties of sanitary officers in tropical colonies. Other papers contributed were on the training of sanitary inspectors and of health visitors.

Medical Officers of Health and "Encroachments."

At the conference of medical officers of health Professor HAROLD KERR (M.O.H., Newcastle), in his address from the chair, touched upon what he called the famous "Encroachments" Report of the British Medical Association. Professor Kerr said: "The inquiry into the charges against the public services was conducted [by the Association] fairly and dispassionately, although by the representatives of the persons who believed themselves to be aggrieved. Their verdict regarding the public health services was in effect 'Not guilty, but don't do it again.' They had to confess as the reasons for various clinical undertakings, lack of any existing means to cope with what was admitted to be an urgent social need, or the inability of private practitioners to meet that need adequately. Local authorities," Professor Kerr continued, "do not want to burden themselves with the cost of schemes for treatment, but they are compelled by public demand, in the absence of efficient alternative, to undertake the work themselves. There is no doubt that more skilled service could often be given in municipal clinics by part-timers than by junior and relatively inexperienced whole-time assistants, if the first claim of private practice could be provided for so as to obviate unpunctuality and irregularity of attendance. Take an ante-natal clinic. Compare the relative values of a part-time doctor practising his or her profession actively, and becoming more proficient every day, and a young man or woman, of no great seniority, who is shut off from active practice, and quickly loses the little knowledge of obstetrics that he or she originally had. Which is the more helpful to the woman suffering from some slight but potentially dangerous defect in her approaching confinement? While the immediate gain to the authority, both in practical results and financially, may sometimes be seemingly considerable, such a whole-time specialist post proves in most cases a mere cul-de-sac, offering no prospect of professional or material advancement to the holder; if not soon relinquished it results only too often in a narrow and cramped outlook, which greatly depreciates the efficiency of the officer. Whole-timers, in general, have been caught comparatively young and drilled more or less into the methodical ways of the office. In this respect the part-timer frequently fails in his record-keeping. Doctors were ever bad business men, but what keen business man was ever a good doctor?"

The New Health Unit.

Dr. A. B. MCMASTER gave the conference a review of the new arrangements in public health administration consequent especially upon the recent passing of the Local Government Act. He mentioned the desirability that each autonomous county district health unit should have at least one voluntary hospital and one county hospital within its boundary; hence the area served by the respective new county hospitals appeared as a possible basis for the review of county districts. The result would be that in each such area one county district authority or combination of such authorities would be the local sanitary authority—the body given power for the prevention of disease—while the county council would be the authority co-ordinating the treatment. The dissociation of these two sides of public medicine was not ideal, and the disadvantages would be minimized if the administrator of the county district health unit was authorized to carry out on behalf of the county authority any treatment schemes in the district concerned.

Dr. R. M. F. PICKEN dealt with the place of school medical inspection and treatment in the public health service. He referred to the statement by the Council of the British Medical Association in its recent Annual Report (*Supplement*, April 19th, p. 137), that it had decided to approach the Ministry of Health when suitable opportunity offered in regard to the central control of the medical services at present dealt with by the Board of Education, and that it was inquiring how far the local health authorities had power to refer to their health committees the question of school children. This decision would be welcomed by the public health service, and it was to be hoped that the opportunity of approaching the Ministry would occur soon.

Diseases of Domestic Animals from the Human Standpoint.

A lecture was delivered to the congress by Dr. O. C. BRADLEY, Principal of the Royal Veterinary College, Edinburgh. Diseases, the same or similar, in the lower animals and in man, he said, were often mutually illuminating. Diseases of the lower animals always held out the promise—frequently in vain, unhappily—that they would throw light on the disease of man. For example, when the *Field* distemper investigation was initiated there were those who hoped that some truth or other would be revealed that would solve or simplify the problem of human influenza. Though the hope did not appear to have been fulfilled, the investigation had nevertheless excited the interest of the comparative pathologist scarcely less than that of the veterinary practitioner. Canine distemper belonged to a group of diseases which, to the pathologist and clinician, had much mystery and fascination, and were at the present time the subject of intensive study. One interesting feature of virus diseases was that the virus might occur in different strains with different potentialities. There were said to be three different strains of the virus of foot-and-mouth disease, which strains were not mutually protective. Dr. Bradley dealt in special detail with two diseases of domestic animals which affected the well-being of man and in which both the economist and the pathologist were deeply concerned—namely, bovine tuberculosis and *Brucella* infection. With regard to the latter, he mentioned that although, fortunately, up to the present, Britain seemed to have enjoyed comparative freedom from this disease, it was possible that the freedom was more apparent than real. Up to a few weeks ago the total number of cases on record was seventeen, but in one issue of the *British Medical Journal* (May 10th) no fewer than five cases of a distinctly suspicious character were reported.

The recent outbreak of psittacosis was the subject of a paper read in the Section of Preventive Medicine by Dr. S. P. BEDSON. He said that the demonstration of a filterable virus as the cause

of psittacosis had found ample confirmation. Although undoubtedly filterable, the results would suggest that the virus at times was more filterable than at others. The commonest way in which infection from bird to man occurred was by direct contact. In the case of birds which were carriers, an intimate degree of contact was necessary for infection to ensue; but in the case of an acutely ill parrot it was obvious from the available epidemiological evidence that the disease could be transmitted to man without direct contact. From man to man infection did not spread readily, so that the disease never assumed the form of widespread epidemics like those of influenza, but there were scattered foci—house epidemics, each centred on a sick bird. In view of this fact the disease should be readily stamped out by putting an embargo on the importation of parrots at the first sign of trouble and forbidding the sale of the birds until the danger was passed.

We hope to deal with the later proceedings of the congress in our next issue.

CARE AND AFTER-CARE IN TUBERCULOSIS.

REPORT OF THE JOINT COUNCIL.

IT is a common complaint from persons responsible for the care of tuberculous patients that only too often the good results achieved by the sanatorium are frittered away for lack of adequate provision for the after-care of patients. The prognosis in many cases of tuberculosis is dictated as much by economic factors as it is by lesions in the chest; in other words, the patient's chances of survival in good health will depend as much as on anything else on whether he can or cannot get work of a kind that is suitable to a person in his physical condition. Laborious work, occupations calling for prolonged mental effort, or that must be carried on in unhygienic surroundings, invite relapse; but even in trades without these glaring defects the ex-patient may be at a disadvantage as long as he has to compete for employment with ordinary healthy people. Numerous schemes for the after-care of tuberculous patients are based on an appreciation of these facts; so many, indeed, that in 1924 the Joint Tuberculosis Council formed a special committee to survey "the employment of the consumptive," with special reference to "schemes at present in existence." This committee has so far prepared three reports, the last of which, recently published, consists of a detailed analysis of most of the existing agencies for the employment of ex-patients.[1]

After-care Committees.

From its survey of the activities of 124 care and after-care committees, the employment committee arrives at the general conclusion that all aspects of treatment and convalescence, and all work concerning propaganda, visiting of patients in their homes, provision of extra nourishment on medical grounds, and provision of medical appliances, should be the immediate responsibility of the medical staff of the tuberculosis department; but that all cases where financial assistance to patients and families is considered necessary after investigation; questions of part maintenance of homes while patients are undergoing treatment in sanatoriums or hospitals; advice about other organizations to which patients may be eligible to apply for assistance; submission of applications on patients' behalf; questions relating to employment of certain patients in ordinary or sheltered industry; and the organization of voluntary effort, should be referred by the tuberculosis officer to a subordinate officer with duties similar to those of the almoner in certain hospitals.

Attitude of Employers.

The difficulties attending efforts to find employment for tuberculous patients are brought out clearly in the second section of the report, which deals with the attitude of industrial concerns towards the employment of consumptives. In order to obtain the opinions of certain important firms, the employment committee approached 220 employers of labour on the question of absorbing ex-patients in industry, making it clear that from the medical standpoint the aim would be to recommend only ex-patients who could be certified as non-infectious. To this appeal the committee received fifty-five replies, varying, of course, in detail, but nearly all pointing to the conclusion that ordinary industry can contribute nothing of great importance to a solution of the problem at issue. Particularly in times of industrial depression would it be difficult, in fact almost impossible, to find in ordinary industry enough openings for consumptives competing in a limited market with healthy individuals. The fact that tuberculous patients are liable to relapse is very widely known, and is another factor militating against their employment by most firms. To workers in the tuberculosis field, says the report, the challenge of industry is to raise the percentage of those who are capable of being reabsorbed into ordinary industry.

Employment in Sanatoriums.

In the third section of the report the committee sets out in detail and analyses communications received from twenty-eight medical superintendents of sanatoriums on the subject of the employment of ex-patients on sanatorium staffs. Most medical superintendents in charge of larger institutions favour the employment of ex-patients in this manner—a consensus of opinion which has great practical importance. As the employment committee points out, if ex-patients formed only 25 per cent. of the 5,400 or so persons employed in sanatoriums, then their combined wages would amount to over £140,000 a year—that is, nearly four times as much as is paid to workers in the various employment schemes and settlements specially set up for tuberculous patients in this country. Employment in this important labour market should, naturally, be given on the understanding that its object is to restore the patient to health and working capacity, and thereby to promote the final aim, which is to increase the proportion of ex-patients that can return to an ordinary working life.

Village Settlements.

The medical, financial, and economic problems relating to the after-care schemes inaugurated by local authorities and voluntary organizations form the subject of the final section of the report. Urban and municipal workshop schemes—for example, the Spero workshops in London, and the factory in the field at Leeds—have not yet passed the experimental stage. At present they have to be so heavily subsidized that unless they prove to be a powerful means of restoring patients to health, or of providing occupations for patients who, on medical grounds, could not be reabsorbed into industry, it is unlikely that many similar schemes will be developed elsewhere.

A great part of this section of the report deals with the village settlements—in particular with the settlements at Papworth and Preston Hall, whose activities are discussed at considerable length. The approximate number of ex-patients employed in the industries in connexion with village settlements in this country is 340. The employment committee was unable to determine the capital expenditure needed for the establishment of these settlements, largely because the finances of the industries are so intimately bound up with the finances of the sanatoriums to which they are attached that subdivision of accounts is not always possible. It points out, however, that at Preston Hall, one of the largest settlements, the estimated capital expenditure of the industries is now £125 per settler; or, if to this amount is added the cost of housing the patient with his family—approximately £400 per settler—the total per settler is about £525. To this expenditure, points out the employment committee, local authorities originally responsible for the patients have contributed nothing, in spite of the fact that they have been freed from infective or potentially infective inhabitants, and have otherwise gained by having houses previously occupied by consumptives available for occupation by healthy citizens.

An important criticism of village settlements is that they cater for so few people. The employment committee suggests that settlers who have been in residence for a

[1] Report of the Employment Committee of the Joint Tuberculosis Council on Care and After-Care Schemes in Tuberculosis. British Legion Press, Preston Hall Industries, Aylesford, Kent. Price 1s. 6d., post free.

number of years, and in whom the disease has been arrested, should be replaced by others likely to benefit from such prolonged treatment under good hygienic conditions.

Conclusion.

In concluding its report the committee expresses the view that the primary aim of all schemes for care and after-care should be to increase the proportion of cases that can enter ordinary industry, rather than to cater for the permanent employment of disabled persons. It may be admitted that with an improvement of the industrial position throughout the country the unemployment figures among ex-patients are bound to fall, but there will always be a large number needing employment under the sheltered conditions of the village settlement.

TEN YEARS OF WELWYN GARDEN CITY.

[FROM A CORRESPONDENT.]

TEN years ago the spot in Hertfordshire upon which now stands a garden city four square miles in area, with 2,500 houses, and a population approaching 10,000, was occupied by open fields and woodlands. The more astonishing achievement, however, of the creators of Welwyn Garden City is that the charm of this countryside, twenty miles from London, has been in no way spoiled by such urbanization. Indeed, the red-tiled roofs and pleasant architecture, of controlled design, the delightful roads, with grass margins and trees, the open front gardens, with backs equally tidy and interesting, and without fences or obtrusive hedges, the abundant recreational provisions, the happy innovations in the nature of communal services, and the evidence everywhere of character and the open mind, make a refreshing picture. Such, by the way, is the intensive production of the cottage gardens, that the output of the area, though a town has now been placed upon it, is greater than it was while it remained purely agricultural land.

To celebrate the tenth anniversary of Welwyn, Sir Theodore Chambers, chairman of Welwyn Garden City, Ltd., with Dr. F. E. Fremantle, member of Parliament for the division, and other directors, entertained the members of the press. One impression made on the mind of the visitor was that, while this is a developing district, there is none of that untidy sprawl to be seen on the growing edge of suburbs. Welwyn is not merely a dormitory for city workers. It is a self-contained township, with residential, industrial, and commercial zones, and a rural belt all round it to preserve its country character. It already houses some forty-five industries, which have their carefully placed factories, with the houses for the workers within walking distance. Factory life in Welwyn Garden City is found in ideal conditions, with clean, roomy buildings, green spaces visible through the windows, and ample opportunities for the workers to take their midday meal at home and to take their evening recreation without being already exhausted by a scrambling journey from town. A number of sectional factories have been built on the unit principle, which are let on lease to manufacturers who do not desire to build their own.

The festivities included a pageant in which the fairies are supposed to leave the garden city to mortals, who thereupon build the city and sell each other houses. But the real story of Welwyn is equally romantic; it is the story of how the late Ebenezer Howard—to whom a memorial has been unveiled in the heart of the town—hastily borrowed £5,000 from Dr. Fremantle and one or two other personal friends to pay a deposit on the purchase of the land, which was going at auction. The vision and courage of Howard and those associated with him, who saw here the second garden city in England (the first, a pre-war conception, being Letchworth) deserve high praise. It should be said that the funds raised in this week of festivities are to be devoted to the provision of a larger cottage hospital; the growth of the place necessitates better provision, though it holds a record in public health. For the last three years the average death rate has been 5.66 per 1,000 (compared with 12.46 for England and Wales), and the infant mortality rate 20.19 per 1,000 births, compared with 69.33 for the whole country. The birth rate, too, is 40 per cent. higher at Welwyn; whether this has anything to do with the fact that in the cheaper houses a deduction is made from the rent for every child, and an addition made thereto for every lodger, we cannot say. There is an energetic health association, which runs child welfare clinics, schools for mothers, district nurses, and a first-aid centre, as well as the cottage hospital, but this does not seem to have eliminated the private practitioner, seven of whom practise in the town.

Other things in the garden city which the visitors were taken to see included the city stores, with eighty departments under one roof, instead of the usual row of miscellaneous shops; the theatre, with its special acoustic design and modernist decorations; the film studios, where a "talkie" was seen in preparation, and an exhibition furnished house, designed by two architects of the Garden City in consultation with the estate manager—a pleasing middle-class house, showing good workmanship and good taste, and, what is so rarely experienced in the modern dwelling, a harmony between the house and the furniture. Finally, the visitors found their way to the inevitable inn, but a place as little like the traditional public-house as can be imagined. Its gardens and pleasant outside aspect invite the guest to take his refreshment out of doors, and even indoors there are none of the depressing accompaniments of the ordinary licensed premises. The "Cherry Tree" is controlled by the Garden City Company, and is under disinterested management. Here Dr. Fremantle, in proposing the health of the press, claimed for Welwyn Garden City that it met practically the case for the preservation of the countryside as against urbanization and ribbon development, and that it was a type of all that is good in modern town-planning from the point of view of industrial efficiency and welfare, traffic freedom, and public health and amenities.

MEDICAL CONGRESSES, 1930.

THE following congresses and conferences on medical and allied subjects have been announced for 1930. Particulars are given below in the following order: Date, name of organizing body, place of meeting, name of person to whom inquiries should be addressed. More detailed information about these meetings is given from time to time, as it becomes available, in the news columns of the *British Medical Journal*.

June 28 to July 2.—Journées Médicales de Bruxelles. Brussels.

July 3–5.—National Association for the Prevention of Tuberculosis. London. Secretary of Association, Tavistock House (North), Tavistock Square, W.C.1.

July 10–12.—Oxford Ophthalmological Congress. Oxford. Mr. C. G. Russ Wood, 12, St. John's Hill, Shrewsbury.

July 20–25.—International Society of Microbiology. Paris. Dr. St. John Brooks, Lister Institute, Chelsea Gardens, S.W.1.

July 26.—International League for Combating Trachoma. Geneva.

July 26–27.—Belgian Congress of Neurology and Psychiatry. Liège. Dr. Leroy, 30, Rue Hemricourt, Liège.

August.—International Congress of Cytology. Amsterdam. Frau Professor Rh. Erdmann, Berlin-Wilmersdorf, Nassauischestrasse 17.

August 3–10.—International Society of Sexology. London. Professor F. A. E. Crew, The University, Edinburgh.

August 4–9.—International Veterinary Congress. London. Dr. F. Bullock, 10, Red Lion Square, W.C.1

August 5–9.—International Congress of Dermatology and Syphilology. Copenhagen. Dr. S. Lumholt, 45, Raadhusplads, Copenhagen.

August 12–15.—International Union against Tuberculosis. Oslo. Secretary of Union, 2, Avenue Velasquez, Paris, VIII.

August 18–21.—International Congress of Paediatrics. Stockholm.

August 26–29.—British Medical Association Annual Meeting. Winnipeg. Financial Secretary of British Medical Association, Tavistock Square, London, W.C.1.

August to September.—International Congress of Neurologists. Bern.

August.—International Congress on Miners' Phthisis. Johannesburg. International Labour Office, Geneva.

August.—Congress of Northern Neurologists. Stockholm.

September 1–6.—International Birth Control Conference. Zürich. Mrs. Janet Chance, c.o. A. S. Cobden, Esq., 10, Adelphi Terrace, W.C.2.

September 4–7.—German Pharmacological Society. Königsberg. Professor J. Schüller, Pharmacological Institute, Zülpicherstrasse 47, Cologne.

September 7–10.—German Society for Natural Sciences and Medicine. Königsberg.

September 14–18.—International Congress of Physiotherapy. Liège. Dr. Dubois-Trépagne, 25, Rue Louvreux, Liège.

September 15–17.—German Orthopaedic Association. Heidelberg.

September 22–27.—International Congress of the History of Medicine. Rome. Dr. F. Rocchi, Corso Vittorio Emanuele 173, Rome.

British Medical Journal.

SATURDAY, JUNE 28TH, 1930.

MOUNT VERNON HOSPITAL AND RADIUM INSTITUTE.

SOME seven months ago we were able to give an account of the conversion of the Mount Vernon Hospital at Northwood into an institution for the study and treatment of malignant disease under research conditions.[1] It will be recalled that in order to give effect to the decision to divert the activities of this hospital into an entirely new direction, the council of management secured the passage through Parliament of an Act permitting the use of the present land, buildings, equipment, investments, and income of the hospital for any purpose conducive to the attainment of its new objects. The bill necessary for this purpose became law on May 10th, 1929. Since the reorganization of the hospital the medical staff has been augmented by workers from other institutions chosen because of their interest and experience in the radium treatment of cancer, and by the appointment of a pathologist, a physicist, and a radiologist. The intention throughout has been that the clinical and laboratory staffs should work together as a team, the admission of patients being regulated solely according to the needs of the hospital as a centre of research and teaching. The influential committee advising the council of management in these and kindred matters recommended that a medical director should be appointed to co-ordinate the activities of the hospital and to lead the team, and for this post they have been fortunate in securing Sir Cuthbert Wallace, until lately senior surgeon to St. Thomas's Hospital and dean of its medical school.

A further stage in this matter was announced early in April in the course of a statement issued by the National Radium Commission and printed in our issue of April 12th (p. 714). The cardinal feature of the Commission's policy has been the concentration of national radium at a limited number of centres where there are medical schools with complete clinical courses and where treatment of patients can be combined with instruction in approved methods of radium therapy. Of these centres 12 have been nominated for recognition—7 in the English provinces, 4 in Scotland, and 1 in Wales. London has been treated as a separate problem in view of its position as the metropolis of the whole country. Here no centre of the standard type is being set up, but steps have been taken to organize two centres to carry out special work of national importance. One of these, the Westminster Hospital Radium Annexe, has been experimenting on behalf of the Commission with a 4-gram "bomb" in order to determine the value of mass irradiation and long-distance radium therapy. The other London centre, as announced by the Commission on April 2nd, will be for the development of post-graduate teaching in radium therapy, the facilities provided being available for the benefit of qualified medical practitioners from any part of Great Britain. This centre, the statement went on, would be located at Mount Vernon Hospital and the Radium Institute, the two institutions being reorganized for these purposes as a joint teaching centre "under a single control, as far as medical services, teaching, and research are concerned. In all other respects the two institutions will retain their separate identities." Negotiations between the three bodies concerned—the Commission, the Institute, and the Hospital—have since then been actively proceeding, and it is hoped that by the autumn the combined centre for research and teaching in radium therapy will be set up. We understand that already a working scheme has been drafted for affiliation between the Radium Institute in Riding House Street, the pioneer organization of its kind in this country, and the Mount Vernon Hospital at Northwood, whose constitution and supply of beds are particularly well suited to the purpose in view. The advisory committee of the Hospital will be reinforced by representatives of the Institute, and co-ordination of clinical, laboratory, and teaching services will be secured by enlarging the sphere of responsibility of the director.

It is recognized by all concerned in the joint project that one of their primary duties is to increase the number of efficient workers in radium therapy by the establishment of a post-graduate school. This school would be under the control of a managing body reporting to the council of the Hospital and to the committee of the Institute, and comprising members appointed by both the participating bodies, together with representatives of the University of London, the British Institute of Radiology, and the British Post-Graduate Hospital and Medical School now in process of creation. It is proposed that the school thus formed shall be called the Mount Vernon Hospital and Radium Institute National Post-Graduate School of Radiotherapy, the duties of dean being undertaken by Sir Cuthbert Wallace, director of medical services and research at the new Mount Vernon Hospital. For the realization of this far-reaching scheme many things are needed, among them radium and money. An adequate supply of radium will no doubt be forthcoming from the Radium Commission. As regards money, the council of the Mount Vernon Hospital is issuing an appeal for funds to provide additional beds and greater research facilities, with the approval of its vice-patron, the Prince of Wales. That the educational aspect is being kept in the forefront may be judged from the preliminary announcement (published at page 1202) of a four weeks' post-graduate course in radiotherapy commencing on October 6th. The course is to be repeated at later dates, which will be advertised to the medical profession.

POLYCYTHAEMIA OF HIGH ALTITUDE.

DR. CARLOS MONGE'S monograph on what he calls "The erythraemias of altitude and their relation to Vaquez's disease"[1] is a very suggestive physiological and pathological study which shows that much further observation and experimentation of various kinds is still required to elucidate a subject already explained sufficiently to show that many points need further explanation or confirmation. Dr. Monge is professor of pathology in the University of Lima. He and those who have worked with him in the study of mountain sickness and acclimatization to high altitudes have had the advantage of living in a country, Peru, from the capital of which, only 160 metres above sea-level, elevations of 2,400 to 5,000 metres may be easily reached by mountain railway, so that symptoms due to altitude are not necessarily complicated with those due to muscular exertion and fatigue. Moreover, the

[1] *Les Erythrémies de l'Altitude: Leurs Rapports avec la Maladie de Vaquez. Etude physiologique et pathologique.* Par Dr. Carlos Monge. Préface du Professeur G. H. Roger. Paris: Masson et Cie. (2f 5s.)

whole subject has been facilitated by the writings of Barcroft, Harrop, and others during the last ten years, though much was already known before then, Paul Bert's original observation on the richness in oxygen of the blood of the llama in the Peruvian mountains dating from 1882.

Dr. Monge agrees, of course, that the polycythaemia of high altitudes represents a reaction to compensate for the diminished oxygen tension in the inspired air (and consequently also in the blood), and that this diminished oxygen tension is the cause of mountain sickness and of all the allied acute and chronic disturbances. The secondary polycythaemia and the associated symptoms he speaks of as a kind of "erythraemia," although by many writers the latter term is reserved for the Vaquez-Osler disease (splenomegalic polycythaemia), no certain cause of which has yet been discovered, and which is, therefore, an apparently primary disease of the bone marrow. Even the worst cases of "erythraemia" of high altitude are, indeed, obviously secondary, since, though in many respects they may closely resemble cases of the Vaquez-Osler disease, they are immediately remedied by residence at the coast or low elevations. Dr. Monge explains the steps by which the body adapts itself to high altitudes—at first by the spleen emptying its reserve of blood into the circulation and subsequently by the increased production of erythrocytes—leading to perfect acclimatization in suitable individuals, but not in others. Occasionally acclimatization may be lost, not only by individuals who have come from low altitudes and have acquired it, but even by individuals born in high altitudes and in whom acclimatization was therefore congenital. The only cure for such cases is shown to be descent to lower elevations, if not to the coast. What has happened in such cases? Apparently there has arisen some superadded hindrance to the diffusion of oxygen from the inspired air into the blood in the lungs.

It is certainly tempting to regard the various kinds of cases grouped together by Parkes Weber as examples of secondary polycythaemia of cardio-pulmonary, or rather of pulmonary origin (including "Ayerza's disease," from syphilitic disease of the pulmonary arteries), as due to interference with the pulmonary diffusion of oxygen, causing insufficient oxygen tension in the bone marrow. Such cases would therefore to some extent be analogous to cases of "erythraemia of high altitudes," excepting that the latter can be cured by descent to low altitudes, whereas in the former (being already in low altitudes) the oxygen tension could only be increased artificially, and probably only temporarily, by compressed-air chambers, etc. Dr. Monge, following suggestions of Harrop and Heath, goes so far as to believe that some of the cases clinically regarded as examples of the Vaquez-Osler erythraemia, and therefore of a primary disease of the bone marrow, may really be secondary to an interference with the pulmonary diffusion of oxygen due to a structural abnormality in the pulmonary epithelium. In regard to the subject as a whole he recognizes the importance of individual and familial constitutional proclivity. His monograph is of great interest from both the physiological and the pathological point of view, and is indispensable for those studying the problems of acclimatization to high altitudes. The observations on cases of what Dr. Monge calls "chronic mountain sickness" are of extreme importance. Obviously, in various kinds of polycythaemia further estimations are needed regarding the diffusion of oxygen from the air to the intra-pulmonary blood.

MEDICAL ADMINISTRATION IN INDIA.

THE Indian Statutory Commission returns in the second volume of its report[1] to the problems of recruitment for the medical services in India and submits detailed recommendations, together with the reasons that have led it to put them forward, for meeting the special difficulties presented by these problems, a survey of which appeared in the first volume of the report. In summarizing the relevant passages from the survey (June 21st, p. 1141) we directed special attention to the Commission's view that the maintenance of the European elements in the various services depends on the Government's ability to provide European doctors for the treatment of officers and their families. This view is once more emphasized in the second part. "European officers of the services," states the Commission, "lay great stress on the continued provision for themselves and their families of medical treatment by European doctors." The Commission, regarding such provision as essential, recommends that no change should be made in the present Devolution Rule 12, which gives the Secretary of State in Council power to prescribe the number of Indian Medical Service officers to be employed in the provinces, and the terms and conditions upon which they shall be employed; and that no effort should be spared to secure an adequate number of European recruits for the Indian Medical Service to implement this fundamental obligation. It will be recalled that, on the recommendation of the Lee Commission, All-India recruitment for the services employed in the transferred departments of the Government ended in 1924, with the one exception that each province was required to employ a certain number of officers of the Indian Medical Service. This exception was imperative not only because of the Government's obligation to secure European medical treatment for the European personnel and their families, but because it was obviously necessary to maintain a medical reserve for war. Recognizing, then, the need for encouraging European recruitment to the Indian Medical Service, the Commission proceeds to consider the conditions upon which future recruits to this and to other All-India services are to be employed. For the present members of the services it recommends simply that their existing rights and privileges shall be safeguarded; for new recruits it recommends the same rights and privileges, with the exception of the right of premature retirement. The Commission assumes that, as soon as possible after the new constitution is settled, a full explanation of the changes involved, and their implication for the services, will be made public, and that every possible step will be taken to ensure that prospective candidates are fully informed of the conditions under which they will serve. In such circumstances the Commission suggests that to grant recruits the right of premature retirement on pension before any case for it has been established would throw an unjustifiable burden upon Indian revenues. It does not pretend to be able to forecast the future of the services or to guarantee that conditions may not arise in which able and energetic officers will find their continuance in them impossible; it therefore puts on record its strong view that there should rest upon the Secretary of State for India a special obligation to see that officers who may join the All-India services hereafter are treated in the spirit of the recommendations of the Joint Select Committee in regard to the services; in short, that every precaution should be taken to secure to the public servants the career in life to which they looked forward when they were recruited. Turning to public health problems, the Commission points out that the proper working of medical services, as of other matters which are entrusted to the legislative and administrative control of the provinces, demands co-operation between the Centre and the provinces,

[1] Cmd. 3569. Report of the Indian Statutory Commission, vol. ii. London: H. M. Stationery Office. 3s.

and between province and province, setting up as an example of the kind of methods which it thinks should be adopted the recent institution of the Council of Agricultural Research. Improvement of public health in India, the increase in the supply of trained nurses and doctors, and the reduction of infant and maternal mortality, might be materially promoted if there were a wider central organization staffed by competent officials, both men and women, whose business it would be to co-ordinate and encourage the work that is so much needed in these directions. In the Commission's view such a bureau would have functions that would extend beyond the range of the Central Medical Research Institute which was recommended two years ago by Sir Walter Fletcher's Committee.[1]

THE LISTER INSTITUTE.

IMPORTANT changes in the staff of the Lister Institute of Preventive Medicine are foreshadowed in the recently issued report[2] of the governing body. Towards the end of this year Sir Charles Martin, director of the Institute, and Professor Arthur Harden, head of the department of biochemistry, will complete their term of service, having been on the staff of the Institute for twenty-seven and thirty-three years respectively. The governing body places on record its high appreciation of Sir Charles Martin's administrative ability, his many scientific achievements, his gift of securing harmony among the scientific staff and other workers who have enjoyed the hospitality of the Institute, and his services to commissions and committees engaged in the investigation of problems of preventive medicine. In equally felicitous terms it refers to Professor Harden's long and distinguished service, and recalls with pleasure that it was for researches pursued in the laboratories of the Institute for over twenty-five years that he received the high honour of the Nobel Prize in chemistry for 1929. Professor J. C. G. Ledingham, at present head of the department of bacteriology, who joined the staff of the Institute in 1905, has been appointed to succeed Sir Charles Martin; and Dr. R. Robinson, who joined the staff of the biochemical department in 1912, to succeed Professor Harden. Before proceeding to its survey of the researches that have been in progress during the year in the various departments of the Lister Institute, the governing body expresses its gratitude to the Medical Research Council, the Department of Scientific and Industrial Research, the British Empire Cancer Campaign, and the International Committee for the Study of Infantile Paralysis for their co-operation and help. With the financial support of the latter body, Drs. Fairbrother and Hurst have completed their research on the path of spread of poliomyelitis virus in the experimental animal. When they started their work the most generally favoured theory of spread was that the virus, entering the body by the naso-pharyngeal mucosa or by the intestinal tract, reached the central nervous system by the perineural lymphatics, and was then disseminated by the cerebro-spinal fluid. The primary lesion was held to be a meningitis which spread along the vessels of the anterior fissure to affect the anterior horn cells of the spinal cord. Drs. Fairbrother and Hurst by minute histological examination and search for the virus during both the incubation period and the period of symptoms found, on the contrary, that all the facts—especially the mode of advance of the lesions and the distribution of the virus after intracranial inoculation—pointed to the axis cylinders as the chief paths of the infective agent. Their experiments suggest the conclusion that meningitis never occurs in the early phases, but that the disease begins as a primary degeneration of the anterior horn cells accompanied by foci of interstitial inflammation in the interior of the brain and cord. Moreover, whatever the route of inoculation, histologically the infection spreads from above downwards, while the first symptoms are nearly always referable to the lumbar cord. The virus occurs most abundantly in those regions which show the most marked changes. Dr. Fairbrother, investigating the serum therapy of poliomyelitis, showed that serum from a horse that had been successfuly immunized by repeated intramuscular inoculations with a filtrate of poliomyelitis virus possessed antiviral properties comparable with those of human convalescent serum. It is hoped that this horse serum may be made available for therapeutic trial in man. Attempts to obtain complement-fixation with poliomyelitis virus as found in cord emulsions and filtrates and convalescent human and monkey serums have been consistently unsuccessful. Complement-fixation occurred with the serum of the immunized horse, but it occurred also with normal monkey cord as antigen. Drs. Fairbrother and Hurst have started experiments with a view to discovering whether coincident vaccinia can modify the reaction of the central nervous system to poliomyelitis. In later issues we hope to touch on other matters of outstanding clinical importance discussed in this report.

THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS.

THE annual report on the Museum of the Royal College of Surgeons of England by the Conservator, Sir Arthur Keith, contains the reports of the curators of the several departments, together with prefatory notes by the Conservator. A prominent position is given this year to the subject of research. As is the case with all the great museums—the British Museum, the National Gallery, the South Kensington Museum, and others—the museum of the College has always been a place of research in the sense that workers from all parts are continually referring to it for information which may possibly bear on the subject of their investigations. But research work carried out within the walls of the College, although it has always existed to a certain extent, has hardly been recognized as one of the normal functions of the institution; it has never been definitely organized, and has been carried on in spite of inadequate equipment and financial support. These matters have now been corrected. The council has had an excellent laboratory erected, with adequate equipment for scientific work; it has also allotted some of the rooms of the old building to the exclusive purposes of research. Further, thanks to the effort of the president, Lord Moynihan, the College is now in a position to award scholarships, three of which will be available at an early date—namely, the Beaverbrook, Melchett, and Bernhard Baron scholarships, each yielding its holder £500 per annum. The Royal College of Surgeons has thus taken its stand as a centre of research. It will probably be found that the work undertaken at the museum, when compared with that conducted at other centres, is coloured to a large extent by the fact of its connexion with the museum. Successful experiments of such a nature as to allow of their results being placed as specimens on its shelves would seem to be appropriate to the normal working of a museum. Macewen's experiments on bone-grafting, the specimens from which are included in the collection, may be taken as a good example of this type of research. The annual report of the Conservator shows that the museum is a hard-working institution. Limitations of space permit of mention merely of a part of the work—that more especially of interest to medical men. The additions to the museum will be on view from July 3rd to 26th, and they include more than 150 pathological specimens illustrative of diseases of almost every part of the body. Among those of more than usual interest may be mentioned a fine series

of tumours of the testicle, a specimen of extensive ossification of the scar tissue around a gastro-enterostomy opening, hookworm disease, composite odontoma of the jaw, multiple deposits of melanotic sarcoma in the liver of a child secondary to a primary growth in the mother, generalized osteo-sclerosis of the skeleton secondary to carcinoma of the prostate, congenital hyperostosis affecting various parts of the skeleton, calcifying round-celled sarcoma of bone, congenital atresia of the aortic arch in a man, aged 54, and a cornual pregnancy. There is also a large and representative series of joints, constituting the Strangeways Collection and illustrating the lesions of osteo-arthritis, rheumatoid arthritis, Charcot's disease, and gonorrhoeal and pneumococcal arthritis. A series which should attract the attention of surgeons consists of a number of trephined prehistoric Peruvian skulls. The results in most instances are quite perfect, without the least trace of inflammatory reaction, and are probably to be explained by the fact that the indication was merely to provide sufficiently large exits for the spontaneous evacuation of demons in otherwise healthy individuals.

TROPICAL VETERINARY MEDICINE.

SOME time ago we drew attention to the findings of a Colonial Office Committee set up, under the chairmanship of Lord Lovat, to consider the improvement of the Colonial Veterinary Service. The scheme of reorganization put forward included a number of suggestions, some of which have already been put into operation. It was proposed, for example, to institute a number of post-graduate scholarships to enable graduates with a degree in the biological sciences to take a veterinary qualification, or veterinary surgeons to take a science degree. This has already been done, and there will be awarded a number of these scholarships of the value of £250 a year, tenable for a period of up to four years. This is regarded as an interim scheme which will be in operation for ten years. By that time, it is hoped, the attractions of the service will have become obvious to the schools, and undergraduates will take a science degree and a veterinary qualification simultaneously. This will be rendered the easier by the fact that from 1931 the qualifying veterinary course in this country will extend over five years. A few weeks ago the Colonial Office gave effect to a second recommendation and appointed a chief veterinary adviser in the person of Mr. R. Eustace Montgomery, a veterinary surgeon with wide colonial experience and an excellent research record. One of the greatest drawbacks that the newly appointed colonial veterinary officer had in comparison with his medical colleagues was the absence of any post-graduate instruction in tropical veterinary science. This is the more surprising as Britain has three diploma courses in tropical medicine—at London, Edinburgh, and Liverpool Universities. The close relationship existing between medicine and veterinary medicine has long been recognized by the medical profession in these islands; that this is even closer in the Tropics has been shown by the fact that many colonial veterinary officers have attended the relevant parts of the human courses at these schools. But the veterinary officer has many special parasites and diseases within his own province. The Lovat Committee realized this and put forward certain suggestions, which we are pleased to announce have been acted upon by the University of Edinburgh and the Royal (Dick) Veterinary College. Beginning in October of this year, there will be held jointly by these two bodies a course for those study[illegible] tropical veterinary medicine (D.T.V.M.Ed.). [illegible] will be [illegible] the D.T.M. and H.Ed., will occupy six [illegible] alls [illegible] arallel with the tropical medical curri- [illegible] diploma in [illegible]tance. [illegible] has much in common. The course [illegible] course, like [illegible] further e[illegible] parasitology and entomology, [illegible]s, and run [illegible] of oxyge[illegible]riology, animal nutrition and [illegible] with which [illegible] [illegible]gieue, animal breeding in the Tropics, epizoötology, animal diseases in relation to man, utilization of animal by-products, and so on. The teaching will be essentially practical, aiming at the instruction of the young veterinary officer in the science of his profession rather than in the art of clinical veterinary medicine, a subject which, even more than human tropical medicine, can only be taught satisfactorily in the Tropics. Edinburgh is fortunate in the close relationship which exists between its university and its veterinary college. Members of the British Medical Association will remember that Principal Bradley of the Royal (Dick) Veterinary College was president of the Comparative Medicine Section at the Edinburgh meeting in 1927. Edinburgh is particularly fortunate, too, in having available members of the staffs of both institutions qualified to teach the various branches of the subject. The university has always been associated with overseas interests, and by this prompt recognition of the needs of the Colonial Veterinary Service, Edinburgh has again justified its claim to be a great imperial university. We congratulate it on the active steps it has taken to provide a diploma course which should do much to improve the health and the material prosperity of the overseas Empire.

LIGHT AND WORK.

A MOST interesting series of experiments have been carried out by a committee of the Department of Scientific and Industrial Research on the effect of distribution and colour on the suitability of lighting for clerical work. The rapid increase in the efficiency of common illuminants, which has been one of the results of the application of science to industry in recent years, has now made it practicable to employ for ordinary purposes a lamp that gives a colour closely imitating daylight. High claims have been made for the advantages of this artificial daylight. The committee has conducted an extended series of tests of these lamps under laboratory conditions, and these tests have been supplemented by full-scale trials under more practical conditions in several Government offices. The first tests were made in the National Physical Laboratory at Teddington, where a room was fitted up so that both the distribution and the colours of the light admitted to the room under daylight conditions could be simulated by artificial means. An artificial window was fitted, which admitted artificial daylight from a variety of lamps, and the room had also interior fittings for semi-indirect pendent lamps. The relative illuminations under these different conditions were estimated and charted, the intensity of the illumination being made as nearly equal as possible. Tests extended over six weeks; relays of clerks, three at a time, were employed at tasks with which they were thoroughly familiar. There were some differences of opinion among them about the light they found most agreeable to work in, but artificial daylight coming from the dummy window gave by general consent the most comfortable artificial lighting, fourteen out of eighteen observers being agreed on that. Indeed, it was remarkable that this sham window light was preferred to twice the illumination provided by pendants with semi-indirect bowls and tungsten vacuum lamps. It was evident that not the power of the light determined the choice, but the quality. Further, when the dummy window was replaced by a normal daylight window it was found that there was general preference for this, notwithstanding that the arrangements were made in such fashion that the source of the light received was unknown. Full-scale experiments were carried out in some Government offices. Trials were made also in an engineering office, employing upwards of thirty men, and the result of these was a practically unanimous acceptance of movable individual lights over the drawing-boards combined with a

[1] Illumination Research, Technical Paper No. 10. The Effect of Distribution and Colour on the Suitability of Lighting for Clerical Work. London: H.M. Stationery Office. 1930. 6d. net.

few larger units for general lighting. Various forms of artificial daylight were included in the trials, but there was no marked preference for these, and the lamps finally adopted were pearl or ordinary obscured lamps. In rooms where ordinary clerical work was done the evidence obtained was quite inconclusive. Where contrast was not apparent ordinary diffusing glassware could be substituted for the coloured diffusing medium without the difference being detected. The Teddington laboratory tests suggested that, with lamps giving artificial daylight colour, adequate intensity might be less than with uncorrected lamps, but the trials indicated that for clerical work the adequacy figure was practically the same for the two types, adequacy being gauged as the intensity at and over which complaints of insufficient light did not arise, a figure that has been rising slightly during the last few years. In all these trials the daylight lamps or fittings were the usual commercial articles. Tests showed that they cut out only the minimum of red and yellow necessary to produce the daylight effect. There was objection to high intensity blue light from direct ceiling fittings in low rooms, probably because of its "cold" effect. In basement rooms the best results were obtained from panels or artificial windows in the walls combined with indirect ceiling fittings or ceiling panels. It is in this type of room that artificial daylight has an advantage, especially where office accommodation is expensive. The conclusions reached are that natural daylight is without doubt the best form of illumination, and that where this is insufficient and needs to be supplemented by artificial lighting for many hours in the day, then artificial daylight is superior to ordinary artificial light for reinforcing the natural light.

STAPHYLOCOCCAL INFECTIONS.

THE second instalment of this year's volume of the *Guy's Hospital Reports*[1] opens with Sir William Hale-White's sympathetic memoir of Sir Alfred Fripp and his manifold activities. This is followed by an interesting symposium on staphylococcal infections, which occupies a large part of the issue. The first of these eight papers—on the natural history, prognosis, and treatment of staphylococcal fever—is by Dr. J. A. Ryle, who, following in the philosophical footsteps of Sir William Gull, takes a wide view of the subject, and points out that general staphylococcal infection is much better understood when regarded as a specific fever like pneumonia or enteric fever. Staphylococcal septicaemia is usually secondary to a cutaneous focus; it may lead to a natural fixation abscess (always a favourable sign), and is best treated by a copious fluid intake, six pints daily for an adult, good nursing, and early detection and discrimination in the opening of abscesses; vaccines and chemotherapy, Dr. Ryle adds, are probably best avoided. He particularly notes the frequency of sweating in all fevers due to infection by a staphylococcus. As would be expected from his recent Lettsomian Lectures, Dr. H. W. Barber deals thoroughly with skin lesions. "The mild, transitory, and superficial staphylococcal lesions of the skin are usually caused by an *albus* strain, the deeper, more inflammatory, or chronic ones to an *aureus*, or occasionally a *citreus*." He sets out in tabular form a list of staphylococcal dermatoses, with the strain usually responsible for each and the site of infection, and follows this with a comparison in parallel columns between staphylococcal and streptococcal skin infections. Mr. J. L. Joyce contributes a study of the renal cases which form a small but important group of staphylococcal diseases. It is generally agreed that in these cases the cocci reach the kidney through the blood stream from some peripheral focus of infection; accordingly, the treatment of any staphylococcal lesion in the deeper tissues should begin with that of the focus from which it has been derived. While on this point Mr. Joyce insists that a boil or carbuncle must not be opened until it has formed pus, and that the utmost gentleness must be practised in all manipulations concerned in its treatment, using the sharpest of instruments and avoiding all such procedures as squeezing. In regard to the secondary kidney lesions, he suggests that in the early stages a conservative attitude should be adopted towards surgical treatment. This contribution is followed by notes of two cases of staphylococcal perinephric abscess, one by Dr. Hugh Barber and the other by Dr. W. J. Cotton. Dr. J. F. Venables reports two cases of severe non-Addisonian anaemia due to gall-bladder infection with haemolytic staphylococci; Dr. L. J. Witts gives an account of staphylococcic septicaemia complicating Addisonian anaemia; and Dr. F. A. Knott writes on the differentiation of active and inactive leucocytosis.

HINTS FOR MEDICAL AUTHORS.

To the May number of *Guy's Hospital Gazette* Dr. R. D. Gillespie has contributed a useful article on the "Writing of medical papers." His object is to guide Guy's men who may feel called upon to add to the already vast output of medical literature. He mentions four varieties of medical publication: the paper that contains a new discovery of wide application, the paper that records and tabulates the factors involved in the original discovery, the monograph or summary of medical knowledge in a particular field, and didactic publications mainly constituted by textbooks. A more cynical writer might perhaps have included a fifth variety. For the construction of the literary edifice Dr. Gillespie lays down admirable rules. Thus the purpose and scope of the paper should be clearly stated. Sources of reference should always be verified. Tables and graphs should be kept to the minimum necessary for the reader's understanding. A summary of the results and of the conclusions drawn is necessary. While finding the definition of literary form for medical works fairly easy, Dr. Gillespie feels diffident in offering reflections upon style. He is sure, however, that a good style can be acquired; and instances as a proof the achievement of R. L. Stevenson, who laboured at the craft of literary workmanship and "played the sedulous ape" to masters of prose. Editors no less than readers would be grateful for the observance of Dr. Gillespie's four fundamentals of good style: brevity, rhythm, the correct use of words, and a knowledge of grammar.

THE AGE INCIDENCE OF CARCINOMA.

DRS. T. R. WAUGH and T. L. FISHER have recently contributed to the *Canadian Medical Association Journal*[1] a statistical analysis of the age distribution of 1,736 cases of carcinoma (all histologically verified) studied in the Department of Surgical Pathology of the Royal Victoria Hospital, Montreal, from 1915 to 1928. They do not find that the average age of incidence of malignant disease is becoming earlier. If, therefore, the real age incidence has not changed, it follows that the education of the public is not bringing patients to hospital earlier in the course of the disease. Taking the data as a whole, the age incidence of cancer in women is on the average about 5 years earlier than that in men, but, of course, the data are not numerous enough to allow of very satisfactory comparison of the sexual incidences for one and the same site. Cancer of the breast, an almost exclusively female site, contrasts strongly with cancer of the lip, a predominatingly male site.

[1] *Canadian Medical Association Journal*, vol. xxii, No. 5, May, 1930, pp. 618-627.

The former shows as heavy an incidence at 40 as at 60, and then a decline, the latter a steady increase to the age of 55 years, and but little decline thereafter. The data analysed by Drs. Waugh and Fisher support the suggestion that carcinoma arising from glandular epithelium tends to occur earlier in life than that from squamous epithelium, with two main exceptions—the cervix uteri and the prostate, which derive their epithelium from the mesoderm.

INTERNATIONAL PAEDIATRIC CONGRESS.

THE second International Paediatric Congress will meet in Stockholm from August 18th to 21st. The morning sessions will be devoted to the discussion of subjects chosen by the Swedish organization committee, of which Dr. I. Jundell is chairman and Dr. Nils Malmberg secretary; and the afternoon sessions will be kept open for the reading and discussion of individual papers. At the morning session on August 19th Dr. Alfred F. Hess, New York, will open the scientific proceedings with a paper on the biological effect of direct and indirect ultra-violet irradiation. For the morning session on August 20th the subject will be the physiological and pathological significance of the thymolymphatic system; and for August 21st, the psychology and psychopathology of childhood, their significance as a branch of paediatric research and teaching, and their application in medico-social work. These three subjects were chosen from the large number that were proposed by the national committees. Applications for membership should be in the hands of the committee as soon as possible, the latest date being July 20th, and applicants are asked to state whether they wish to attend the special performance of the opera on August 20th and to be present at the congress dinner on August 21st. Dr. J. C. Spence (3, Eslington Terrace, Newcastle-on-Tyne), who is secretary of the British committee, will supply information about the programme and travelling arrangements and about tours to Dalecarlia, Jamtland, Trondhjem, and Visby, which have been planned to follow the congress, and will send printed forms of application for membership and for the booking of rooms in Stockholm.

As already announced in these columns, the eighth International Congress of the History of Medicine will be held in Rome from September 22nd to 27th, 1930. The Italian Government has given the congress its support, His Majesty the King of Italy has been pleased to grant his distinguished patronage, and His Excellency the Head of the Government has accepted the presidency. The Italian Embassy hopes that individuals and institutions connected with medicine in the United Kingdom will participate as widely as possible in the congress. Detailed programmes, and special terms for travelling, may be obtained from the general secretary, Dr. F. Rocchi, Corso Vittorio Emanuele 173, Rome.

THE annual meeting of the Royal Medico-Psychological Association will be held at Oxford in the Sir William Dunn School of Pathology from July 1st to 4th, under the presidency of Dr. T. Saxty Good. At the afternoon session on Tuesday, July 1st, Dr. Good will deliver his presidential address on the history and progress of Littlemore Hospital. The morning sessions on Wednesday and Thursday will be given up to the reading of papers, and on Friday Professor G. M. Robertson will open a discussion on out-patient clinics. The social functions include garden parties at Littlemore and Warneford Hospitals, and at Nuncham Park, a civic reception in the town hall, and a reception by the Regius Professor of Medicine and Lady Buzzard at Magdalen College. The annual dinner will be held on July 2nd in Christ Church Hall.

Nova et Vetera.

A DOCTOR'S BILL OF 1824.

CHARLES DARWIN demonstrated the biological relationship of cats and clover. The familiar and fragrant pink clover needs the help of the bumble bee to fertilize its flowers. Field mice destroy the bumbles' nests and eat their grubs and honey. Cats kill the mice and thus indirectly help to fertilize the clover. No doubt there are other enemies of the field mice which keep their numbers down, but the above is a succinct account of one of the episodes of the struggle for existence. In a somewhat like manner we think that it might plausibly be argued that the Royal College of Physicians was responsible for the success, if not for the invention, of homœopathy. The College forbade anyone to practise physic within its jurisdiction without its licence. Consequently general practitioners could not charge for advice, but only for drugs supplied. Notoriously this led to over-drugging, for if the practitioner was to earn his living he must supply many mixtures, draughts, boluses, powders, and pills. The success of homœopathy was due to its abandonment of all drugs but the most inoperative, and in the smallest quantities.

These reflections were started by the perusal of an old doctor's bill, which Dr. F. H. Rudge of Lostwithiel, Cornwall, has kindly sent to us. It is an account rendered presumably in 1824 to Captain Boger of the Royal Marines, for drugs supplied and for attendance on him and his family by Mr. William Burgess, Surgeon, of Lostwithiel. It seems to have been promptly paid in February, 1824, but it had been running for some time, for the first item is dated May, 1822. The total was £6 3s. Nearly all of it was for "Mrs. B.," including one guinea for "Delivery." There was but little variety in the medicines, which consisted chiefly of "Powders No. 4," and occasional anodyne and laxative pills. Mrs. Boger had a supply of these No. 4 powders eighteen times between May 26th and June 25th, so it is to be hoped that they did not contain any very active ingredient. A charge of 2s. 6d. for bleeding occurs only once. Although, as a rule, attendances were not charged for as such, when Mr. Burgess was "Called in the Night" to Master B. he charged half a crown for the visit, besides charging for two laxative powders, a 2½ oz. mixture, a blister and dressing as well on the same date, so it would seem that this was more or less of an emergency call.

The confinement apart, no one item amounted to more than half a crown. Powders were charged at 6d. each. The charge for anodyne pills was 1s., and for laxative pills 1s. 6d. for an unspecified number. There are long and irregular intervals between some of the dates of items, which suggest that the family needed no attention or were away from home at those periods.

We know of no writer who comes near George Eliot in lively delineation of medical matters in the country at about the time of this account, and to her pages we turn, not in vain, for an illustration of the drug-taking habits of a country matron. In *The Mill on the Floss*, Chapter IX, the following dialogue occurs. The scene is the house of Mrs. Pullett (born Dodson), and she, her husband, and her sister are the speakers.

> "There's 'the pills as before' every night, and the new drops at eleven and four and the 'fervescing mixture 'when agreeable,'" rehearsed Mr. Pullett, with a punctuation determined by a lozenge on his tongue.
>
> "Ah, perhaps it 'ud be better for sister Glegg, if *she'd* go to the doctor sometimes, instead of chewing Turkey rhubarb whenever there's anything the matter with her," said Mrs. Tulliver, who naturally saw the wide subject of medicine chiefly in relation to Mrs. Glegg.
>
> "It's dreadful to think on," said aunt Pullett, raising her hands and letting them fall again, "people playing with their own insides in that way! And it's flying i' the face o' Providence; for what are the doctors for, if we aren't to call 'em in? And when folks have got the money to pay for a doctor, it isn't respectable, as I've told Jane many a time. I'm ashamed of acquaintance knowing it."

Mr. Pullett piously kept all the empty medicine bottles, etc., as a kind of anticipatory monument to his wife; an

attention which she did not resent, but took pride in, thinking of the astonishment of the neighbours "when I'm gone."

The name of William Burgess of Lostwithiel appears in the list of Members of the Royal College of Surgeons in London from 1800 to 1824. (It was not until 1843 that this corporation became the Royal College of Surgeons of England.) We learn through Dr. Rudge from Mr. Boger of Lostwithiel, the grandson of Captain Richard Boger, that the latter was born in 1781. He belonged to a very old Cornish naval family, and saw much service as a Marine officer. He is mentioned in James's *Naval History of Great Britain* as taking part in a cutting-out expedition off the coast of Denmark in 1808. His brother was Admiral Edmund Boger, and his cousin Admiral Richard Boger.

It is an instance of the irony of fate that, while the lieutenant of Marines finds a record in the roll of naval fame, neither his admiral brother nor cousin is to be found there, worthy as they seem to have been.

FIBROSES OF THE HEART.

THE ST. CYRES LECTURE.

FIBROSES of the heart was the subject of the St. Cyres Lecture, delivered by Dr. JOHN COWAN on June 4th at the National Hospital for Diseases of the Heart, with Dr. FREDERICK PRICE in the chair.

It was sometimes useful, said Dr. Cowan, to take stock of our knowledge, and to inspect critically the opinions in vogue and those likely to develop in the future. During the past thirty years many points which at one time were discussed only in laboratories had come into clinical practice. Only recently, for instance, had the significance of syphilis in heart disease been realized.

The diagnosis of myocarditis was not always easy. Associated myocarditis was always present in acute endocarditis, and it might also arise in many acute infections. In the case of one patient with acute rheumatism, who had returned to work after fourteen days in bed, a sudden relapse had followed; after another short period in bed the patient had again returned to work; the result had been an attack of sudden acute dyspnoea; he had died, and on post-mortem examination an inflammatory lesion of the aortic valve, spreading to the mitral cusps, was found, and there were septal lesions affecting the bundle of His. The diagnosis of myocarditis might also be made in cases of progressive heart failure without obvious cause. Slides were shown of a case in which, without an obvious heart lesion, the apex beat had steadily moved further and further from the mid-line. The case had begun with an attack of bronchitis, which cleared up without causing any apparent injury. Later, another attack of bronchitis was also shaken off successfully, but instead of recovering the patient had grown worse, and later had died. At necropsy myocarditis was found.

The cardinal symptom of coronary disease was, of course, pain. If a ligature were tied about a limb, and the muscles were then forced into continuous action, a sense of discomfort, and subsequently of severe pain, was produced; nor was it relieved except by removal of the ligature. The pain of intermittent claudication was similar to the pain of the ischaemic limb. In aortic disease with incompetence the diastolic blood pressure was low, so that there was some degree of ischaemia even when the patient was at rest. It should be remembered that an injured heart might perform well as long as no undue demands were made upon it. One of his patients with angina had been driven home in a car; he had then jumped out and run up the steps, and this exertion had been sufficient to induce an attack. It had been atypical in that the patient was restless and talkative throughout, and had tried to relieve the pain by belching up wind. The pain had subsided and his pulse had recovered for a time; then the pain recurred, the pulse failed, and finally the patient had died in the attack. Throughout it his pulse had quickened only very slightly. In a second case of angina, seen in hospital, the patient had given evidences of severe pain and anxiety. The pulse rate had risen from 80 to 100, and its strength had gradually failed. The patient had died six months later of an infarct of the left coronary artery. In another patient, a stevedore, there had been sudden violent dyspnoea. He was forced to lie down for a while, but recovered and returned to work. A few days later he had had a similar attack, in which he died. It was discovered post mortem that he had aneurysm of the heart. In yet another patient, this time a policeman, the chief symptom had been shortness of breath. He was a very stout man, and had been admitted to hospital, where he had recovered. Later he died, and at post-mortem examination his heart had been found to show the condition of ischaemic fibrosis.

It was important to recognize the connexion of abdominal symptoms with infarct of the heart. In one patient, a medical man, there had been pain round the xiphoid cartilage associated with flatulence and indigestion. The patient had believed that he suffered from gall-stones. Another patient, a woman suffering from nausea and vomiting, who had been diagnosed as dyspeptic by all who had examined her, sat up in bed and died suddenly of a ruptured heart. One patient with infarct of the heart had been subjected to abdominal laparotomy before Dr. Cowan was called to see him.

In some cases electro-cardiography was useful in the diagnosis, but too much was not to be expected. Deformities in the electro-cardiogram depended on an imbalance between the right and left hearts, and might disappear from the picture if, on healing, the balance was again restored. Prognosis, said the lecturer, was difficult. Most patients with angina died suddenly; in myocarditis the prognosis was at its best if recurrence could be prevented. Syphilitic cases were hopeful. In coronary disease there were wonderful recuperative powers if the treatment was sufficient, and the treatment lay in the one word "rest." Rest for several months was essential, and it must be absolute. Two of his patients had died at stool. In some cases large doses of bromide, even up to 60 grains a day, were valuable if the patient could not be persuaded to rest otherwise.

Dr. Cowan closed his lecture by saying that the poets had known all about the heart long before the scientists. He quoted from *King John*: "My heart hath one poor string to stay it by"—in other words, the bundle of His. And from Samuel he quoted: "His heart died within him and became as a stone," which he diagnosed as pericarditis with calcification.

During the lecture Dr. Cowan showed interesting slides of myocardial lesions, including periarterial infiltration and fibroses, macroscopic and microscopic appearances of gumma, subacute interstitial fibrosis, and infarct of the coronary arteries accompanied by rupture or followed by massive clotting. He showed also a number of electrocardiograms, giving a description of the cases to which they belonged. At the conclusion the chairman proposed a vote of thanks, and presented Dr. Cowan with the St. Cyres medal.

Ireland.

Medical Benefits in Northern Ireland.

THE National Health Insurance (Medical Benefit) Bill has passed its second reading in the Northern Senate, an amendment for its rejection having been defeated by 9 votes to 4. In opposing the measure Mr. Long said that it was causing profound dissatisfaction in the rural areas, where it was considered unnecessary. Viscount Charlemont explained that the bill was designed to bring the Northern Ireland insurance scheme into line with that obtaining in Britain, both in the rate of contribution payable and in the benefits provided for insured persons. The principal reason for the Government's policy was the fact that the amount of sickness among insured persons and the general death rate in Northern Ireland were both much higher than the corresponding rates in Britain. Under the bill the insured person himself became a contributor to the cost of any medical treatment or any medicine he received: thus there could be no suggestion of "pauper test." The

arrangements made after negotiations with representatives of the dispensary medical officers were such that overlapping between the two services would be avoided, and the bill gave effect to an agreement with the dispensary medical officers to ensure that they would not receive double remuneration for attending the same person.

Royal Medical Benevolent Fund Society of Ireland.

The annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held on June 18th at the Royal College of Surgeons, Dublin. The annual report stated that in spite of the fact that a few of the branches were inactive the receipts for the year had increased by £50, mainly as the result of larger collections. Thanks were recorded to the Leinster Branch of the British Medical Association for valued assistance given during the year. A joint circular letter seeking increased support for the Benevolent Fund had been issued in the names of Dr. J. P. Shanley, honorary secretary of the Leinster Branch of the British Medical Association, and of the central secretary of the society to all practitioners in the area of the Branch. The cost of printing, postage, and office expenses was borne by the Leinster Branch. It is difficult to appraise the result of this effort, but it is notable that the branches of the society in the area covered by the Leinster Branch of the Association are chiefly those from which increased returns have been received. It can be safely said, therefore, that the appeal has not been without effect. The number of grants awarded during the year was 86, compared with 83 in the previous year. The amount disbursed in grants was £2,104, compared with £1,863 in 1928-29. The beneficiaries included 7 medical men, 13 orphans, and 63 widows. The average amount of the grants was £24, compared with £22 in 1928-29, and £23 in 1927-28. A total of £4,326 was received from the estate of the late Mrs. Anne Hepburn. Dividends and interest yielded an increase of £128, and donations and subscriptions paid through the central treasurer amounted to £196 17s. 6d., being one shilling less than last year. No special donations from individuals were received, but those paid through branch treasurers amounted to £507, an increase of £50. The society expressed its thanks to the Irish Medical Association for its grant of £10, and to the Dublin Biological Club for a donation of £5. The British Medical Association remitted the sum of £69 11s., being the amount of subscriptions collected by the Association. Were it not for the activity of the Association most of these subscriptions, which are gathered all over the world, would be lost to the society. While expressing its pleasure at the increased strength of the Fund as evidenced by recent additions to the capital and by the increase in receipts from the branches, the Central Committee states that the majority of the members of the profession still remain deaf to its appeals for support. The need of the moment is to enlist the help of others to take the places of those trusted supporters who have gone. Sir John W. Moore, senior honorary secretary, again emphasized the fact that that society was the only body in Ireland charged with the duty of caring for the needy doctor and for the widows and orphans of members of the profession. Small as it was, the aid given meant a little extra comfort for the afflicted, support for the widow in her fight against adversity, better clothing for the children, and help in their education. In some cases it provided the very means of life itself.

Overcrowding at a Mental Hospital.

The necessity for early treatment of mental disorder was urged by Dr. John Mills, medical superintendent of the Ballinasloe Mental Hospital, in the annual report of the institution for 1928, in which he stated that only about a third of the new patients admitted during the year were received within the first three months of their illness. These patients numbered 219—122 men and 97 women; 198 were committed under the Dangerous Lunatics Act, and 3 as criminal lunatics. The principal factor in 45 cases was ascribed to inherited insanity, which was also stated to be the cause in the cases of congenital mental deficiency. Dr. Mills condemned the adherence to forms of criminal procedure in conveying patients to mental hospitals, but admitted that this seemed unavoidable under existing legislation. He also directed attention to the steady increase in the number of patients in the Ballinasloe Hospital, which, he asserted, had been overcrowded for the last twenty-five years to an extent that hampered efficiency and retarded recovery. While advising that no further additions should be made to the hospital, he suggested that a mental hospital should be built by the County Roscommon to provide sufficient accommodation for its own patients. Congestion in the Ballinasloe Hospital was a constant source of irritation to excitable patients. Moreover, nurses worked under great disadvantages, and their rooms were also overcrowded. The total number of patients under treatment during the year was 1,773. A memorandum of inspection, appended to the report, states that the estimated accommodation of the hospital is 1,317. Patients discharged as recovered numbered 51 men and 33 women; 9 were discharged as relieved or not improved. Including both sexes the average percentage of recoveries was 38.4. Ninety-five deaths were recorded, the chief causes of death being pulmonary diseases, senile decay, and exhaustion. A satisfactory report was given of the hospital farm, which employed over 200 men. The net profit for the year in working the farm amounted to £1,302. In regard to the general resources of the hospital the financial statement showed a credit balance of £2,739.

Infants' Hospital, Dublin.

At the recent annual meeting of St. Ultan's Hospital for Infants, Dublin, Dr. Dorothy Price stated that 283 cases had been treated in the wards during the year, an increase of 88 on the figure of the previous year; 59 per cent. of the patients were under 4 months of age. It was satisfactory to note that the death rate showed no corresponding rise, but had fallen steadily for the past three years. In 1927 the death rate was 34 per cent., in 1928 32 per cent., and in 1929 it was 25 per cent. Among contributory causes was increased efficiency in treatment resulting from eleven years' experience, and improved accommodation. The new wing had been in use for a year, and the single cot wards fitted with vita glass and opening on to a balcony aided recovery in certain cases. The benefit of more extensive accommodation was felt also in the out-patient department, where 6,192 cases were treated, an increase of over 1,000 on the number of the previous year. Dr. A. H. Davidson, in seconding the adoption of the report, stressed the necessity for fuller instruction in the medical curriculum in regard to the care of infants in health and disease, and emphasized the value of the hospital's work in the provision of skilled nurses. Dr. J. P. Shanley said that paediatrics was the Cinderella of medical science, and referred to the value received for money expended on the care of children in their earliest years.

Scotland.

University of Glasgow.

A GRADUATION ceremony was held in the Bute Hall of Glasgow University under the presidency of Principal Rait, on June 18th, when a number of representatives of Switzerland, America, and France received honorary degrees, besides a number of distinguished Scotsmen and Englishmen. Among those upon whom the LL.D. degree was conferred were Lewellys Franklin Barker, professor of medicine, Johns Hopkins University, Baltimore, U.S.A.; Julius Berend Cohen, emeritus professor of organic chemistry, University of Leeds; and James Kerr Love, consulting aural surgeon to the Glasgow Royal Infirmary. Eight bachelors of medicine received the degree of M.D.

A meeting was held in the Randolph Hall of Glasgow University on June 18th, when Professor Thomas Hastie Bryce, M.D., F.R.S., was presented with his portrait. Professor Bower presided, and after the portrait had been unveiled it was accepted for custody by Principal Rait. The chairman said that Professor Bryce came to Glasgow in 1890, having graduated in medicine at Edinburgh. In 1892 he was a university lecturer, and was engaged for a long period at Queen Margaret College in the medical training of women. In 1909 he was transferred to the chair of anatomy. Principal Rait remarked that Professor Bryce, in addition to his other qualifications, was a historian, and had performed the remarkable feat of

adding several centuries to the human history of these islands, as well as contributing greatly to our knowledge of the anthropology of their prehistoric population. In the course of his reply Professor Bryce recalled some of the developments that had taken place during his forty years' connexion with the university, and mentioned that his grandfather, who was born in 1765, had matriculated at the University of Glasgow.

Northern Infirmary, Inverness.

A gathering of the clan Donald was held at Inverness on June 13th, when the freedom of this burgh was conferred upon three distinguished representatives of the clan, the Right Hon. J. Ramsay MacDonald, Prime Minister, Sir Murdoch Macdonald, M.P. for Inverness, and the Right Hon. Stanley Baldwin, M.P. Mr. Baldwin described himself as one of the Children of the Dispersion, whose mothers' people had lost their home for having been out in the rebellion of 1745. In connexion with the gathering a visit was paid to the newly reconstructed Northern Infirmary of Inverness, and a tablet recording the names of the first list of subscribers to the institution was unveiled by the Prime Minister. The Mackintosh of Mackintosh, president of the hospital, occupied the chair, and said that on Christmas Day, 1925, he had made an appeal for £100,000 towards the reconstruction; to-day the new wards in the Infirmary had been opened after £99,647 had been actually subscribed. He characterized this as a splendid response from the Highlands. The directors still hoped that a grant would be made by the Government towards the cost of the hospital. The clan Donald had taken a special interest in the Northern Infirmary when it was originally opened in 1824, and he hoped that the Macdonalds would live up to their reputation. All the clans had taken a great interest in the Infirmary. As regards the Government grant, he hoped that the Prime Minister would use his influence to melt the ice-block of the present Chancellor. In referring to the grant, the Prime Minister, in his reply, said that he had that day received an official communication about a conference that the Government had held, and he was able to say that, in respect of the responsibility which Parliament had assumed for the provision of the Medical Services of the Highlands and Islands, the question of making a grant from this fund to the Northern Infirmary would be sympathetically and favourably considered. The amount would be settled by the Secretary for Scotland and the Chancellor of the Exchequer. In addition to this grant, however, the Government would give a sum of £1,000 to aid diagnosis and treatment, provided that £2,000 was raised by voluntary subscription before the end of the year. Subsequently, during a tour of the hospital, Sir Alexander Grant of Logie intimated that he would give a contribution of £3,000 a year for seven years towards the reconstruction fund.

Deaf Persons in Scotland.

At a meeting of the Scottish Association for the Deaf, held in Glasgow on June 18th, Sir John M. MacLeod, Bt., appealed for a departmental inquiry into the work of deaf persons, which would also have the object of avoiding the economic waste arising from this cause. Sir John suggested that the inability to hear or speak was a greater disability than that of blindness, for it struck at the root of the intellect; the deaf and dumb were cut off from the rest of the community. The outside public was sympathetic towards such persons but uninstructed; if it were realized that deafness imposed a handicap which was not merely physical but intellectual, ameliorative treatment would be forthcoming. The blind had been receiving preferential treatment for a long time from the State and from local authorities, and as support for the deaf was a sound policy it was desirable that a departmental inquiry should be held. A resolution was passed asking for a complete investigation by the Government into the conditions and needs of the deaf and dumb, and affirming that vocational training should be provided for deaf boys and girls in order to enable them to become self-supporting and to compete in industry with those of normal capacity. On the same day a meeting of the Glasgow Society for the Education of the Deaf and Dumb was held. It was stated that surplus funds were being gradually accumulated by the society for the purpose of undertaking a scheme of vocational training. The chairman referred to the progress that was being made in dealing with the after-care of ex-pupils; it was stated that a nurse had paid 1,000 visits to deaf and dumb ex-pupils during the year, while employment had been found for twenty-two girls and women during that period.

Royal College of Physicians of Edinburgh.

The Dr. Alexander Black Lecture, which is a triennial function of the Edinburgh Royal College of Physicians, was delivered on June 20th by Dr. David Rorie, D.S.O. The lectureship is the result of a bequest of £1,000 made in 1923 by Miss Ann Louisa Black of Castlebank, Cupar, in memory of her brother, Dr. Alexander Black, a former Fellow of the College; the proceeds are expended on the purchase of books for the library, the purchase of apparatus for the laboratory, and for the delivery of a lecture on some subject of general interest in medicine. Dr. Rorie took as his subject folk medicine in Scottish ballad and literature. He pointed out that there were many hundred old Scottish ballads which had been handed down by oral tradition in various forms, and which sometimes bore a considerable resemblance to the ballad lore of other nations. He explained this by the fact that many foreigners had been present as cooks, musicians, and other servitors at the courts of the older Scottish kings, especially of James IV. Many of the ballads had medical interests and medical references, and a subacid criticism of the leeches of ancient days could frequently be detected. Sturdiness in warfare had been glorified in the ballad of Sir Andrew Barton, who made a patriotic speech, according to the ballad, after he had been shot through the heart and brain by Englishmen; the death of this noted Scot had been largely responsible for the disastrous campaign of Flodden. The well-known ballad of a young Scottish knight who had been poisoned by a dish of eels probably accounted for the great prejudice against this fish as an article of food all over Scotland, a dislike which was not found in the southern part of Britain. He referred also to the touching ballad of Bessie Bell and Mary Gray, who, in the last epidemic of plague that ravaged Scotland in 1645, built themselves a bower in the woods to escape infection, which

> "They theekit it ower wi' rashes green,
> They theekit it ower wi' heather,
> But plague cam on them frae the toon,
> And slew them baith together."

University of Edinburgh.

The annual general meeting of the Alumnus Association of the University of Edinburgh was held on June 18th in the Senate Hall of the University, under the chairmanship of Mr. Alexander Miles, F.R.C.S.Ed., the acting president. It was reported that the membership of the Association now numbered 2,098, and that branches had been formed in several parts of the kingdom—for example, in South Wales, East Yorkshire, Birmingham, and Liverpool. The following were elected honorary presidents of the association: Sir James Barrie, the Chancellor; the Right Hon. Winston Churchill, Lord Rector; Sir Alfred Ewing, Principal Sir Thomas Holland, and Sir Harold Stiles. Dr. Logan Turner was unanimously elected to succeed Mr. Miles as acting president. The suggestion was made that a complete list of undergraduates of the university since its foundation should be drawn up; this was remitted to the executive committee for consideration.

Dundee Royal Infirmary.

The annual meeting of the governors of Dundee Royal Infirmary was held on June 9th, under the presidency of Mr. Athole F. Stewart, chairman of the institution, who made a special appeal for funds for the purchase of 500 mg. of radium. The directors, he said, had already purchased 500 mg. at a cost of £7,000, and he expected that an equal amount would be lent by the National Radium Commission. An appeal was also made for £2,000 for the reconstruction of the surgical out-patient department. The ordinary income of the Infirmary in the past year amounted to £33,830, and the ordinary expenditure to £46,939.

England and Wales.

Annual Reports of Medical Officers of Health.

THE Ministry of Health has issued a circular (No. 1119) to public health authorities in England and Wales describing the character of the report which medical officers of health should present for the current year. Although the annual report for 1930 will be more simple in its scope than the full survey report which was required for 1925, it should contain information on certain matters in more detail than has been given in the reports for the last four years. The reasons for this amplification are (1) that the transfer of the Poor Law functions in pursuance of the Local Government Act, 1929, and the other changes effected by this Act, have necessitated a careful survey, by the medical officers of health of counties and county boroughs, of the hospital and other medical services available in their areas; and (2) that the Government's proposals in relation to housing embodied in the Housing Bill at present before Parliament will necessitate the early directing of special attention by medical officers of health into housing defects in their areas and the compilation of accurate records regarding the housing position generally. The circular has been issued earlier than usual in order that medical officers of health may be aware of the heads under which information should be tabulated on these two matters.

Dr. R. A. Askins.

On June 6th the staff of the Bristol Health Department, presided over by Dr. R. H. Parry, medical officer of health, took leave of Dr. R. A. Askins, the retiring medical officer of health for the city and port, on his appointment as Principal Medical Officer to the Government of Southern Rhodesia. Dr. Peters, medical superintendent of Ham Green Hospital, the medical officer with the longest record of service, made the presentation of a pair of handsome etchings. Dr. Parry and other members of the staff expressed the feelings of the subscribers in wishing Dr. Askins God-speed, and emphasized the outstanding ability displayed by him during his term of office. On the same day Dr. Askins was also the recipient of a silver rose bowl, presented by the medical and administrative staffs of the Bristol Education Committee as a token of their esteem and affection. Councillor Giles, chairman of the Hygiene Committee, presided, and members of the different branches voiced the feelings of the subscribers. Dr. Askins, responding, spoke of the six years he had been associated with the Health Department as extremely happy ones, and although he regretted parting company he felt that his new appointment had many attractions; he would carry with him many pleasant recollections of the excellent feeling that had existed between himself and the staff. He also spoke of the considerable development of the school medical service since his appointment in 1914.

Stoke Park Colony, Bristol.

The managers of Stoke Park Colony, Stapleton, Bristol, have appointed the following to the consultant and research staff of the several institutions under their care. Director of Medical Services: R. J. A. Berry, M.D., F.R.C.S., formerly dean of the faculty of medicine, University of Melbourne, and honorary psychiatrist to the Children's Hospital, Melbourne. Consulting physician: J. A. Nixon, M.D., F.R.C.P., professor of medicine in the University of Bristol. Consulting surgeon: E. W. Hey Groves, M.D., M.S., F.R.C.S., professor of surgery in the University of Bristol. Consulting pathologist and bacteriologist: J. Walker Hall, M.D., professor of pathology and bacteriology in the University of Bristol. Consulting oculist: A. E. Ilcs, M.B., F.R.C.S., ophthalmic surgeon to the Bristol General Hospital. Consulting laryngologist: J. Angell James, jun., M.D., F.R.C.S., assistant surgeon to the Ear, Nose, and Throat Department, Bristol Royal Infirmary. Consulting radiologist: T. B. Wansbrough, M.B., D.M.R.E. In making these appointments the managers have acted in accordance with the intentions and expressed wishes of the late warden, the Rev. H. N. Burden. Mr. Burden had already rendered a great service to England and her mentally afflicted children, but he felt that even more could be done by organized study and research, especially along the lines of potential methods of treatment. The appointment of such a staff to Stoke Park Colony, with its 1,750 patients, is therefore a fitting testimony to him and his work.

Harveian Society Dinner.

A large number of Fellows and their guests attended the Buckston Browne annual dinner of the Harveian Society, which was held at the Connaught Rooms on June 19th, with the president, Dr. P. Montague Smith, in the chair. Among the guests of the society were Sir E. Farquhar Buzzard, Regius Professor of Medicine at Oxford; Professor W. Blair Bell, president of the British College of Obstetricians and Gynaecologists; the Rev. T. P. Conyers Barker, vicar of Hempstead Church, Essex; and the presidents of kindred medical societies. Sir Farquhar Buzzard, in proposing the toast of "The Society," said that the Harveian Society, like the other great medical societies, was in effect a post-graduate school, helping its members to adjust themselves to an ever-changing environment. He rejoiced not only in the society's present prosperity, but in the fact that its future had been provided for by a fairy godfather. The president, in his reply, gave an account of the proceedings of the society during the year. Attendances at meetings had been consistently good. The membership had increased from 317 to 329, and, flourishing thus, the society was able to look out not for members, but for quality. He reminded Fellows that the society had made itself responsible for reconditioning and rehanging of the bells of the Harvey memorial tower of the Parish Church at Hempstead, Harvey's place of burial. To do this the society would have to collect four hundred guineas, a trifle in comparison with the nearly £6,000 that was required to restore the tower, and he appealed to Fellows to help to place the bells in position as a very small tribute to Harvey from the society which had the honour of bearing his name. The Harveian Society had been in existence for ninety-nine and a half years; it was, said Dr. Montague Smith, to be his successor's glory to complete the century. Professor Tom Hare welcomed the guests in a charming speech, to which responses were made by Professor Blair Bell, the Rev. Paul Nichols, and Dr. F. J. McCann. A musical entertainment was contributed in the course of the evening by Mr. T. C. Sterndale Bennett.

The Last of the Old Middlesex Hospital.

On Tuesday, June 24th, a Court of Governors met for the last time in the old board room of Middlesex Hospital. The contract for the demolition of the last of the eighteenth century buildings has been signed, and the great board table, the familiar pictures, and the historic panelling, old when the old buildings were themselves new, will now be carefully stored until the board room of the new Middlesex is built and ready to receive them. Prince Arthur of Connaught, chairman of the hospital, spoke on this occasion of the progress made in medicine during the thirty years of this century. It was difficult, he said, to think of a hospital now without x rays for diagnosis, without a deep x-ray treatment plant, without radium and radon, with no clinics for tuberculosis and for venereal diseases, no neurological or orthopaedic special departments, no wards for the treatment of borderline mental cases. Thirty years ago there was no infant welfare department, no organized massage service, and the electrical department was little more than a toy in charge of one of the physicians. The modern hospital had to provide all such facilities, and the new Middlesex, when completed, would take its place in the medical service of the nation. The expenditure necessary to maintain a modern hospital had naturally risen enormously, and, for example, at Middlesex it was £84,500 last year for the main hospital, as compared with £34,000 in 1912. But as a result of such activities, as Prince Arthur pointed out, the nation is not only living longer but is living in greater

bodily comfort. Killing diseases are coming more and more under control, and he holds strongly that, as a national medical service emerges out of the chaos of the past, the great voluntary hospitals will be essential for the carrying out of research and the training of medical men to staff the national service. The new Middlesex means the colossal expenditure, first and last, of £1,100,000, and of this sum less than £300,000 now remains to be found. Already the west wing is fully in use, the new nurses' home is occupied, and the new out-patient department, to deal with the yearly quarter of a million patients, is in working order in the Annexe in Cleveland Street. On Tuesday there ended a chapter in the medical history of London, and the Middlesex Hospital board room closed down with the passing of an epoch in medical science. In the words of the energetic secretary-superintendent of Middlesex, Mr. S. R. C. Plimsoll, this is not a tragedy but a triumph.

Correspondence.

TREATMENT OF EYE DISEASE BY TUBERCULIN.

SIR,—There are several points in Dr. Camac Wilkinson's article in the *Journal* of June 14th (p. 1090) which, in my opinion, are open to criticism.

First of all it would seem a reasonable question to ask Dr. Wilkinson whether he is prepared to make the diagnosis of tuberculous disease of the *eye* on a *general* tuberculin reaction. The whole value of the treatment as regards specificity depends on the answer to this question. In none of the nine cases quoted is there mention of a *focal* reaction, on which Dr. Wilkinson used to lay so much stress. (That the danger of such reactions has been much exaggerated is in accordance with my own experience.) Having regard to the fact that certain authorities will not concede the possibility of tuberculous infection in chronic disease of the eye—apart from certain forms of iritis and a small group of cases of choroiditis—the absence of any reference to a focal reaction is unfortunate.

The analogy between the paths and stages of syphilitic and tuberculous infection is very picturesque, but until such pathological process is definitely proven we can only *conjecture* that the eye lesions in the published cases are manifestations of tuberculosis in the "secondary stage." The fact that the patients made excellent progress while under tuberculin treatment in no way substantiates the claim that the lesions were tuberculous. At the same time, as T.A.F. appears to have been the variety of tuberculin used in diagnosis, it is quite likely that the patients themselves were infected by the bacillus. However strongly we may believe that many chronic diseases of the eye are due to Koch's bacillus, we have as yet no indisputable evidence that they are so caused.

For the past ten years I have been associated in a medical capacity with the honorary surgeons at the Oxford Eye Hospital. We have always been interested in these "doubtful" tuberculous lesions. Some years ago Mr. P. H. Adams and myself tested a considerable number of patients by subcutaneous injections of tuberculin, by the von Pirquet and the blood complement-fixation methods, in collaboration with the late Dr. Inman of the Brompton Hospital. It was only the premature and lamented death of our colleague that prevented a publication of the series. It may, however, be stated briefly that the results were hopelessly inconsistent and of no practical value in diagnosis. In fact, the very inconsistency of the results rendered the tests dangerous in so far as they tended to obscure the value of a careful clinical examination.

In cases where a *focal* reaction is obtained to a tuberculin injection—for example, in cases of keratitis, iridocyclitis, choroiditis—when the Sigma test for syphilis is negative, we are on surer ground. These cases—incidentally not a very large number—are almost certainly tuberculous; they should be treated with tuberculin and will do well. On the other hand in some cases of chronic eye disorder—for example, iridocyclitis, even where a *general* tuberculin reaction has been positive—we have sometimes found "non-specific" antigen such as T.A.B. of value, and more rapid in action than tuberculin. Such "shock" tactics are, of course, well known in certain general diseases of unknown etiology—for example, rheumatoid arthritis and disseminated sclerosis.

The above criticisms may appear ungracious coming from one who owes much to Dr. Camac Wilkinson's teaching during the past twenty years, and who believes that his work has never been rightly appraised in this country; but it is only by the avoidance of injudicious and indiscreet claims of its value that tuberculin therapy will ultimately find its proper place—in the opinion of the writer a not inconsiderable place—in the diagnosis and treatment of tuberculous disease. At the same time I am in complete agreement with Dr. Wilkinson that tuberculin should certainly be used in doubtful cases of chronic eye disease. It will do no harm and can do good.—I am, etc.,

WILLIAM STOBIE.

Department of Ophthalmology, University of Oxford, June 15th.

ETHER CONVULSIONS.

SIR,—I am interested in Mr. Sykes's review of ether convulsions (*British Medical Journal*, June 21st, p. 1123), and in the case which he cites from his own experience. His suggestion that impurity in the oxygen, which is now so often used as an accompaniment of anaesthesia, may be the cause of the convulsions does not appear to me quite to meet the case. In the first place, in many of the cases quoted by others oxygen was not employed until after the onset of the attack. Used then, in Pinson's experience, it seems to have exerted a beneficial effect. In the case quoted by Walton in the *Journal* of July 7th, 1928, the convulsive attack came on independently of the use of oxygen. As far as one can gather most, if not all, the patients were cyanosed before the attacks commenced. I suggest that Mr. Sykes has misunderstood me in thinking that I attributed the convulsions to excess of CO_2; I pointed out, rather, that this was much likelier to have been present in the old days of closed inhalers than under modern conditions. Yet no mention of convulsions is to be found until comparatively recently. Impurity in the ether still seems to me to be the most probable cause. In Walton's case this was definitely found. I merely suggested superheating as a possible contributory cause in the formation of impurities. It would be very helpful in elucidating the matter if the ether, either from the drop bottle or from the container of the particular apparatus, as the case may be, were subjected to careful examination immediately after the occurrence of convulsions.—I am, etc.,

H. P. FAIRLIE.

Glasgow, June 21st.

THREADWORMS AND PRURITUS ANI.

SIR,—In some recent correspondence in your columns regarding pruritus ani, I have seen no mention of the threadworm *Enterobius vermicularis*. Many practitioners, in my experience, believe that the threadworm is an unlikely cause of pruritus ani in adults in this country, and that the parasite, if present, could hardly be overlooked. Unfortunately neither of these suppositions is true. In support of this assertion I may mention that at the moment of writing I have under treatment four adults suffering from this distressing complaint, in each instance acquired in England. The symptoms had lasted, before diagnosis, for from a year and a half to eight years, during which periods the sufferers had had repeated examinations, including sigmoidoscopy, and had received treatment from physicians, dermatologists, and radiologists, without permanent benefit, and without the cause of the irritation having been discovered. Three of the four had been advised to undergo surgical operation as a last resource.

I submit that in any case of nocturnal pruritus ani the first cause to be excluded is *Enterobius*. For practical purposes it may be taken that an active nocturnal pruritus which is stopped instantly by a rectal injection of strong salt and water, and which remains absent for the rest of the night, is due to threadworms. In cases of long standing, however, more exact diagnostic methods are advisable. Eggs may be found in the faeces, but are often absent,

They are more readily detected in scrapings from the neighbourhood of the anus. But it is most satisfying to the patient if the parasites themselves are demonstrated. In one instance the suggestion that *Enterobius* might be the responsible agent was not warmly received by the medical attendant, who attributed the trouble to some obvious haemorrhoids. Accordingly I visited the patient's house after he had retired to bed, and, when the pruritus commenced, a quick local examination with the help of an electric torch resulted in the capture of three female *Enterobius*. Or the worms may be looked for in a returned enema, administered when the irritation is present. A bedpan or similar receptacle should be employed, because the worms usually sink at once in water and are extremely difficult to detect in an ordinary closet pan, especially so as most of the worms passed are contained in the first ounce of fluid returned.

The most important point in treatment is to prevent auto-infection by the mouth, this being the cause of persisting infestation. It is not enough for the patient to wash his hands before meals and after defaecation, as is commonly advised; they must also be scrubbed thoroughly when he wakes in the morning—for the early cigarette and morning cup of tea are particularly dangerous—and again, whenever the skin of the body, or any article of underclothing, has been touched. I have recovered fragments of a worm and several dozen eggs from a single fingernail, and have found a crushed gravid female on an undergarment. Thus it is easy to see how eggs may be smeared all over the surface of the body.

The simplest curative treatment in my experience is rectal injections of salt and water, two tablespoonfuls of kitchen salt to the pint. If this causes griping, reduce the quantity of salt by half, but discomfort after injection is generally due to failure to expel all the air from the apparatus employed. The patient must be taught to give the injections himself, for these are properly effective only when pruritus is felt. An infant's 2-ounce enema bulb is all that is required. The patient lies down with the pelvis raised and injects the fluid; then, without rising, he refills the bulb and repeats the injection once. I have tried giving larger quantities of fluid, and employed more elaborate apparatus, but the results were no better, nor could I find any advantage in giving a preliminary simple enema. When the fluid is passed out the pruritus ceases at once, and the patient feels nothing more until the following night. Sometimes treatment has the effect of making the worms return to the rectum earlier than usual the next day. Thus, if the nightly irritation previously began between 10 and 11 o'clock, on the day following a wash-out it may be felt about 6 or 7 in the evening. With a little practice the whole process takes only a minute or two, and patients who have been tortured nightly for years will be found extremely grateful for so simple a means of securing undisturbed sleep.

I have obtained cure with a week's treatment; usually, however, the wash-outs have to be continued for about six weeks, but given only when pruritus is felt. Within this period all the developing females should have reached maturity and migrated to the rectum. Infestation persisting for more than six weeks suggests self-infection. I have never had reason to suspect any multiplication of the parasites within the body.

Anthelmintics are helpful in reducing the number of worms, but they cannot be relied on to reach those inhabiting the caecal pouches and appendix. It is suggestive that the drugs usually recommended either have a laxative action themselves or are given combined with purgatives. To one man who had not had a night's unbroken rest for several months, I gave as an experiment one day's treatment with santonin and calomel (santonin 2 grains, calomel 1/2 grain, t.i.d.). This had a sharp purgative effect, and the patient remained free from irritation for about a week. The worms expelled were passed alive, suggesting that the calomel was the active agent. Sufferers from an unrecognized threadworm infection often attribute the irritation to constipation, as they have observed that a sharp action of the bowels gives temporary relief.

Sometimes persons in seeking treatment for some late reflex phenomenon due to *Enterobius* omit all mention of pruritus, having been assured that this latter symptom is due to haemorrhoids, constipation, etc. I have had this experience in the case of patients who, respectively, complained of frequency of micturition, gastric hyperacidity, and passage of large quantities of mucus. The sufferer from the last-named complication, having recently returned from the East, had diagnosed it as dysentery, a supposition supported by the occasional appearance of a trace of blood, which came from excoriations around the anus.

For convenience I have called the anal irritation "pruritus." As a matter of fact, the sensation experienced by the subject of infestation with *Enterobius* is not really an itching, but an intolerable, light, rapid tickling caused by the movements of the worms.—I am, etc.,

Royal Army Medical College, S.W.1, June 18th. W. P. MACARTHUR.

THE OCCIPITO-POSTERIOR CASE.

SIR,—I have been most interested in the paper by Dr. Douglas Miller in the *British Medical Journal* of June 7th (p. 1036), and I have carefully noted the excellent advice given by him. I have been particularly interested in his suggestions concerning the treatment of occipito-posterior presentations seen when labour is well advanced. In the last ten years I have dealt with a large number of presentations of this sort, and have on three occasions met with a complication to which I can find no reference in the literature I have consulted on this subject. I refer to face presentations resulting from attempts to deliver by forceps after manual rotation of the head to the L.O.A. position. It will be suggested that this is due to too early application of forceps, but in each of my three cases full dilatation of the os has existed before rotation was attempted. In each of the cases there has been slight contraction of the pelvic inlet, but not to any marked extent. The cases were: (1) a multipara, (2) a primipara, (3) a multipara. In each case under deep anaesthesia, the cervix being fully dilated, manual rotation was done and forceps applied. In each case a face presentation resulted. In cases (1) and (3) this malpresentation was corrected, and delivery of live children was effected by light traction with forceps in a backward direction, the left hand at the same time being in the vagina and pushing the sinciput up to increase flexion. In Case 2 this procedure was also adopted, but extension persisted, and eventually a craniotomy had to be performed. I believe that when manual rotation is carried out in the type of case to which I refer there is a definite risk of the occiput becoming fixed against the pubic arch; and if traction with forceps in the usual direction is employed, extension of the head follows with a resultant face presentation, unless at the same time pressure is applied to the sinciput by the left hand to increase flexion, and traction is made with the forceps in a backward direction. A short time ago I discussed this subject with a well-known consulting obstetrician, and he agreed that this complication had no place in the literature on the subject, and also that he had experienced a similar difficulty.

I was also interested in Dr. Miller's use of the right blade first to maintain the head in the corrected position. For years now in difficult forceps deliveries where the amount of room is limited—whether the case is occipito-posterior or not—I have applied the right blade first. This procedure may be unorthodox, but it is certainly most efficacious. I learnt it from my late partner, Dr. John D. Davies, now of Stafford, who had found this method of application of forceps of great use.—I am, etc.,

Llanelly, June 12th. A. H. D. SMITH.

INSTRUMENTAL ROTATION IN THE OCCIPITO-POSTERIOR CASE.

SIR,—The letter of Dr. Watson in the *British Medical Journal* for June 21st (p. 1153) is interesting. I always use Kielland's forceps, and with this instrument rotation of the occipito-posterior is so easy that this presentation offers no more difficulty than the ordinary anterior presentation. It is hard to understand why Kielland's forceps has not taken the place of the axis traction forceps

in this country; it is the only forceps I use now, and the following are some of its advantages.

1. The head can be easily rotated in posterior and transverse positions.

2. The pull is exerted in the line of true axis traction.

3. It fits more snugly and there is less damaging compression to the foetal head.

4. It is easier to apply than any other forceps, even in the high operation.

5. It will grasp a smaller or malformed head more firmly than will other forceps.

6. It can be kept on until the head is completely delivered, with advantage to the perineum, as it fits so closely to the head that the vulva is not stretched more than by the head itself (due to overlapping of shanks).

The choice of operation in an occipito-posterior presentation in a multipara lies between internal version and Kielland's forceps; in a primipara rotation by Kielland's forceps is by far the best treatment.—I am, etc.,

D. C. WILLIAMS, M.B.

Port Talbot, June 22nd.

GLANDULAR FEVER.

SIR,—In your issue of May 24th (p. 976) Dr. Shulman and I reported on a number of cases under the heading of "An obscure exanthem." Since then I have been able to observe the further history of many of these cases. About 75 per cent. showed slight enlargement of the occipital and cervical glands as well as those along the posterior border of the sterno-mastoid. In some cases the glandular enlargement was more marked than in others. In a number of the cases the spleen became palpable but not tender. The glandular enlargement became palpable towards the end of the second or beginning of the third week, just when the roseolar rash was fading. One of my cases (a man aged 22) was still running a temperature (99.5°) eight weeks after the onset of the illness. His spleen, which was still palpable about a fortnight ago, cannot now be felt; whilst the glands can only be felt in the occipital region. Another case (a man aged 24) had such marked enlargement of the cervical and inguinal glands that a Wassermann test was performed, and proved to be negative.

I have read with interest the detailed descriptions of cases of glandular fever in recent issues of the *British Medical Journal*. The striking resemblance between these cases and those described under the title of "An obscure exanthem" leaves no doubt that, as Drs. Balme and Lowry suggested (June 14th, p. 1110), the latter were cases of glandular fever where the rash was the marked feature.

It would appear, therefore, that in an average case of glandular fever we have three stages:

1. Stage of onset, with pyrexia, rapid pulse, malaise, generalized pain, etc.

2. Stage of appearance of rash in successive crops from fourth to seventh or tenth day of illness.

3. Stage of glandular enlargement, the glands becoming enlarged from about the tenth day onwards. The spleme enlargement follows on the glandular enlargement. This stage lasts in an average case about three weeks, but may be as long as six to eight weeks, or even longer, and gradually leads up to the period of convalescence.

The pyrexia continues during the three stages, by which time the patients have usually lost considerable weight and have become very pale. Some cases may omit the second stage; others may miss the third stage. The latter type of case would naturally reach convalescence much sooner, without any noticeable glandular enlargement. Thus one is led to believe that in the recent outbreak of glandular fever the disease may have been more widespread than was at first apparent; and that many cases not showing the typical rash or the typical glandular enlargement may have been overlooked.—I am, etc.,

M. W. CANTOR.

London, E.1, June 23rd.

TREATMENT OF ASTHMA.

SIR,—With reference to the discussion on asthma, reported in your issue of June 21st, I venture to quote the following paragraph from my address on the use and abuse of the lime salts in health and disease (*British Medical Journal*, September 24th, 1910).

"*Asthma.*—In the attacks there is an excess of free calcium ions in the blood, and in the treatment, both during and between the paroxysms, the intake of calcium in the diet should be strictly regulated. During the paroxysm, not merely antispasmodics, but also decalcifying agents, should be freely prescribed. A milk diet should be rigidly excluded."

—I am, etc.,

JAMES BABE.

Hindhead, June 21st.

SIR,—The importance of the factor of heredity, and the injury caused by milk, were emphasized at the meeting of the Medical Advisory Committee of the Asthma Research Council, the proceedings of which were reported in the *Journal* of June 21st (p. 1133). I am sure that the bottle-fed children of allergic parents have great difficulty in becoming immunized to the proteins of cow's milk. I have found that such babies improve enormously and become able to take their feeds without sickness, constipation, etc., if three or four times a day after meals they receive a few minims of a mixture of ac. hydrochlor. dil., calcii chloride, liquor. strych. hydrochlor., and glycerin. This result is what might be expected from the gastric analyses of many of those cases in which the chief findings were diminution of acid and delayed emptying of the stomach. The chloride content of the gastric mucosa is also apparently impaired. The calcium chloride seems to have two functions: (*a*) activation of the rennin ferment in the stomach; (*b*) activation of trypsinogen of the pancreatic juice. The latter is perhaps the more important.

It is difficult to say if this treatment aborts potential asthma; it probably helps to prevent some allergic manifestation. The proteose reaction found in these cases seems to point to impairment of early stages of digestion. In infants with asthma I have had good results from the same treatment combined with parathyroid 1/40 grain and regulation of diet. These children require weekly cleansing of the liver and bowel with mercury and chalk, or rhubarb and soda, because whenever an attack is impending the stools become markedly offensive. When acetone is present during an attack glucose and sodium bicarbonate are the chief weapons; but glucose alone will not eradicate and cure an asthma of the hereditary type.

Workers in Vienna have recently described an eosinophilous bronchial catarrh of an asthmatic type associated with the expectoration of small pellets of mucus; the catarrh and eosinophilia were completely removed by the intravenous injection of calcium chloride.—I am, etc.,

R. CHALMERS.

Darlington, June 21st.

X-RAY TREATMENT OF TONSILLAR INFECTION.

SIR,—Dr. Warner Collins prefaces his article on destruction of tonsils by diathermy (June 14th, p. 1024) with some disparaging and almost wholly erroneous remarks on x-ray treatment.

In doses such as I have recommended and found useful—namely, "50 per cent. or less of the erythema dose with a 4 mm. Al. filter" (*Journal*, February 1st, p. 216)—x-ray treatment given in the usual fortnightly or longer intervals cannot possibly "lead to dermatitis." Nor can the correct localization of the radiation beam in any possible way reach the thyroid and parathyroid glands. (The portal is about 1½ inches square, behind and below the angle of the jaw, the rays passing in a medial and upward direction.)

Dr. Collins would also appear to ignore the fact that "normal human beings harbour haemolytic streptococci in the mouth and pharynx in a large percentage of individuals examined" (*Textbook of Bacteriology*, Zinsser, sixth edition, 1927, p. 344). What the recent American work on tonsils and their radiation has shown clearly is that the mere presence of organisms in the tonsil crypts is no evidence of their malign activity—rather the contrary. These organisms are essential factors in the normal antibody laboratory, consisting of the tonsil, together with the

rest of the Waldeyer ring of lymphoid structures, and serving the respiratory tract.

What x-ray treatment does is greatly to reduce the number of organisms deep in the tonsil crypts by causing shrinkage and natural drainage (a mechanical gain), and by an apparent or real stimulation of the tonsil's defence mechanism. That it reduces the numbers of organisms has also been shown by its help towards the diphtheria carrier problem; for many observers have reported freedom from diphtheria bacilli within a few weeks of treatment, when other measures had failed.

As a conservative method of treatment x-ray therapy must be held to be superior (in children, and in all but urgent surgical cases in adults, or those with hard, fibrous tonsils and deep pus collections) to any destructive method such as excision or diathermy, because the organ involved is not a remnant or useless appendage, but an active antibody-forming gland.—I am, etc.,

London, W.1, June 21st. J. H. DOUGLAS WEBSTER.

STORAGE OF *X*-RAY FILMS.

SIR,—The following incident may be of interest to those who have to store x-ray films in small country hospitals.

I store the films which have been used during the last year in a lead-lined cupboard adjoining my x-ray room for easy reference. The room in which the cupboard is has been enclosed from a verandah of an annexe to the hospital, and has a stone-flagged floor. I considered they were fairly safely housed, and was therefore somewhat surprised to find the films on fire this morning. The sole cause of the fire was a hot-water pipe connected with the radiator in the developing room. The cupboard with its lead lining has been built over this.

I have had the cupboard under precisely similar conditions for twelve years, and can only conclude that in the present warm weather the heat of the water was raised just to the degree required to set the films on fire. Though the films on the floor of the cupboard were burnt to ashes, and all badly scorched, the woodwork of the cupboard is entirely undamaged owing to its lead lining, which also doubtless saved a bad fire.

The only question is, Would the fire have occurred at all if the cupboard had not been lead-lined, and therefore practically airless? However, the moral is, do not store celluloid even over a hot-water pipe, and even if the floor of the cupboard is not actually touching it.—I am, etc.,

Woburn Abbey, June 16th. M. BEDFORD.

DRUG TREATMENT OF MEASLES.

SIR,—Since last March I have treated 24 cases of measles with pyramidon, and can confirm Dr. Collier's good results, published in the *Journal* of June 14th, and those of Drs. Urquhart and Winchester on June 21st. No case has had any respiratory complications, and by the fourth day nearly all were practically well. Instead of the lassitude and catarrhal condition often observed at this time the children were bright-eyed, cheerful, free from catarrh, and often from rash. The temperature is lowered the first day, and its duration is at least half the usual. In several cases treatment was begun when only Koplik's spots were present, and these cleared up very quickly, being practically well in three days, and the patient having scarcely any rash.

Two brothers were seen on a Friday, one having the rash, the other a big crop of Koplik's spots; both were practically well by the Monday. Two young infants were treated in poor homes. One had the chest full of crepitations when first seen, the other an abscess under the upper lip, which was opened. In four days both were well, but there is no doubt that without the specific treatment both would have been seriously ill. Another child, aged 2, was first seen by me after being ill two weeks; broncho-pneumonia was present. After two doses the patient had a good night and the lung trouble cleared up at once.

The dose I give is 1 grain for each year of age, with a maximum of 4½ grains for any age, given four-hourly. When the temperature falls the drug may be stopped unless some other symptoms show that the disease is active. The drug may be given as tablets, crushed in jam, or buried in a sultana.—I am, etc.,

June 20th. HOWARD B. GLADSTONE,
Honorary Medical Officer, Sydenham Infant Welfare Centre.

SIR,—Dr. J. I. Collier's paper on the treatment of measles with amidopyrin is a welcome confirmation of the results obtained by me in the treatment of measles with the same drug and published in the *British Medical Journal* on July 12th, 1924. These results, which are now the outcome of twenty years' experience, and comprise hundreds of cases, were summarized by me as follows:

> "It therefore seems to me that the drug acts as promptly in measles as quinine does in malaria, or the salicylates in rheumatic fever. A drug which checks the onward march of the symptoms, and particularly the development of the rash, surely has the right to be called a specific remedy."

It is regrettable that my article has been completely ignored in England for six years, because I am convinced that early administration of the drug in all cases of measles would not have remained without effect on the mortality statistics. Archibald Hoyne (*Illinois Medical Journal*, October, 1929) advocates the use of this drug in measles, and states that it has been used since 1924 at different children's hospitals in Chicago.

Since the drug must be exhibited in the early stages of the illness and gives prompt relief only in uncomplicated cases, it will always remain the remedy *par excellence* for measles in general practice, and although beneficial, will not be nearly so striking in its results in hospital practice, where chiefly advanced and complicated cases are seen. The final verdict on this question must therefore lie with the general practitioner, whose duties give him unique opportunities for studying the disease in all its stages.—I am, etc.,

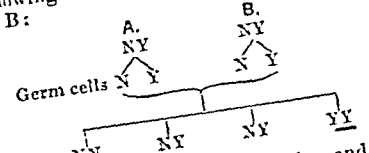
Liverpool, June 14th. MAX LOEWENTHAL.

SIR,—Dr. J. I. Collier, in his note in your issue of June 14th (p. 1093), states that he could find only one reference to the use of amidopyrin as a specific in measles—that of Dr. Loewenthal in the *British Medical Journal* of July 12th, 1924. In the *St. Bartholomew's Journal* of December, 1929, appeared a report of a case of measles cured in one day; the writer further mentioned that he found the drug of equal value in scarlet fever (12 cases). In the *Illinois Medical Journal* of October, 1929, Dr. Archibald Hoyne corroborated these results, and drew attention to the fact that amidopyrin or pyramidon had been used in the Children's Memorial Hospital in Chicago since 1924 with "astonishing results." As to dosage, I myself have given as much as 5 grains night and morning to a contact aged 16 months, who had developed coryza, cough, malaise, and temperature 103°; in forty-eight hours (that is, after 15 grains in all of the drug) the child was perfectly well and exhibited no delcterious effects from the drug. That such a specific as amidopyrin in measles has not a more widespread use demonstrates how sceptical we are, as a profession, of any new therapeutic agent.—I am, etc.,

Bradford, June 16th. JAMES MORRISSEY, M.B., Ch.B.

STERILITY IN WOMAN.

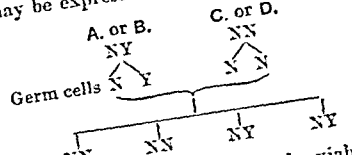
SIR,—Like Dr. Gair Johnston, who writes in the *British Medical Journal* of June 14th (p. 1112) on sterility in woman, I should appreciate the views of gynaecological experts, not only on the interesting case of so-called "incompatibility," which he cites, but also on the following tentative explanation, based on simple Mendelian principles.



Geneticists have recognized for many years the existence in the chromosomes of factors, or genes, which, when present in a double dose (that is, in the homozygous condition) render the organism non-viable. Many such "lethal factors" are found throughout the animal and plant kingdoms, and some peculiarities in human pedigrees have been explained by assuming their presence. For example, an individual receiving the factor for haemophilia from both parents is incapable of prolonged existence, and dies either before birth or soon after. Further instances are found in the pedigrees of colour-blindness, brachydactyly, and other conditions.

Now let us take the case given by Dr. Gair Johnston. Let A be the man who had illicit connexion with the woman B, C be the woman A married, and D the man B married; and let Y be the lethal factor and N the factor

for normality. Then the genetical constitutions of the four individuals concerned are as follows:



A—NY. B—NY. C—NN. D—NN.

The following scheme shows what happens when A is mated to B:

Now the individual YY is non-viable; and if it dies so early that the menstrual rhythm of the mother is not disturbed (that is to say, almost immediately after fertilization) the chance that the couple A B will *appear* to be sterile is as great as 1:3. This chance does not seem to me too small to account for apparent sterility throughout the reproductive period, and it certainly affords a reasonable explanation of delayed fertility.

The subsequent unions between A and C and between B and D may be expressed thus:

That is to say, all their offspring will be viable.

I fully realize that I am juggling with probabilities and assumptions, and that even if the explanation I have put forward happens to be correct, there is no remedy for such "incompatible" cases; I merely offer the suggestion in case it may interest Dr. Gair Johnston, and in the hope that experts may give their views on the matter.—I am, etc.,

V. C. ROBINSON.

Chelmsford, June 16th.

MEDICAL ASPECTS OF CIDER.

SIR,—The use of cider as a preventive or curative agent in certain conditions remained based on tradition without scientific confirmation until the latter part of the last century, when Dr. Denis Dumont[1] recorded the result of a number of experiments and personal observations. Starting out for an explanation of the absence of uric calculi and other gouty phenomena in the cider districts, though such conditions were not infrequent in the wine-drinking districts, he enlarged the scope of his inquiry. In France the facilities for experiment in hospitals were greater than obtain with us, for the common beverage given to patients is red wine diluted; hence he was able to substitute cider for the wine without difficulty. It was soon found that diuresis was promoted by cider, thereby contrasting with the wine, and the question then arose as to which of the constituents was the active one. By trial with equivalent amounts of solutions of malic acid, Dumont concluded that malic acid was the agent sought. Since his day we have learned that the chief difference between wine and cider or perry is that wine contains tartaric acid or acid tartrates, while these are completely absent from both cider and perry when these are in pure condition. Wine contains some amount, usually small, of malic acid, much of which, however, is turned into lactic acid during maturation. Wines, then, contain tartaric, malic, and lactic acids, ciders only malic and lactic acids, apart from small amounts of volatile acids in both.

If the physician, guided by this knowledge, advises his patient to use cider (or perry) as a beverage and avoid the products of the grape—advice which Dumont records in various successful cases—it behoves him to be sure that his patient is not taking tartaric acid, and so undoing the action of the other acid; this he cannot be sure of at the present time, for many beverages on the market named "cider" are in fact strongly sophisticated with tartaric acid. To the practised palate the alteration in flavour gives a clue that some foreign acid (tartaric or citric) is present; but a simple test will tell whether any inordinate amount of tartaric acid is present. It is carried out thus: to a third of a tumblerful of cider about half a teaspoonful of milk of lime is added slowly, and, stirring well, further small additions are made, until the liquid *begins* to change colour to a deeper and browner hue, showing that the acids are nearly neutralized. Then a small further addition of the cider is made, so that the original colour may be restored; the liquid must be in a fairly acid condition, for, when it is alkaline, malate of lime and tannin are also precipitated. After thorough stirring the glass is left till the following day, when, if tartrates are present, a fine crop of very bright little sandy crystals (orthorhombic, with obliquely cut ends) will have formed and settled out or become attached to the sides. With a pure cider no such crystals are seen. By adding different amounts of tartaric acid to a pure cider it was found, as a rough means of estimating, that an addition of 0.8 gram per litre gave a very marked result; with 0.4 gram the deposit is not so definite, but becomes more easily visible when about one-fifth of the volume of 70 per cent. alcohol is added, and a further twenty-four hours' delay afforded; the visible limit appears to be about 0.2 gram per litre with addition of alcohol and a forty-eight hours' crystallization period. Since the milk of lime is rather a messy reagent, other forms of calcium were tried; the best seems to be liquor calcis saccharatus, but it is rather slow in action, though very fine large crystals are eventually deposited.

It is regrettable that more approach from the scientific side has not been made on the effects of cider or its acids on the human frame; from Denis Dumont's work it may be presumed that the beneficial action in the vomiting of pregnancy, renal colic, etc., is due to an elimination of noxious matters by way of the kidneys. Obviously, in making further observations care should be taken that the experimental material is true cider.—I am, etc.,

HERBERT E. DURHAM, Sc.D., M.B., F.R.C.S.

Hereford, June 12th.

[1] *Les Propriétés médicales et hygiéniques du Cidre et sa Fabrication.* Third edition, 1833.

Obituary.

WE regret to record the death of Dr. JAMES HAMILTON, which took place at his home in Glasgow on June 10th. He received his medical education at the University of Glasgow, where he graduated M.B., C.M. in 1820, and obtained the F.R.F.P.S.Glas. diploma in 1896. He held appointments as assistant physician to the Victoria Infirmary, Glasgow, and as assistant physician and anaesthetist to the Glasgow Samaritan Hospital for Women. His publications include a "Case of double congenital hydronephrosis in a young man" in the *Transactions* of the Glasgow Pathological and Clinical Society, 1905, and "Cases of cerebro-spinal fever" in the same journal, 1906. During the great war he held a commission in the Royal Army Medical Corps and was attached to the 4th Scottish General Hospital. James Hamilton was an active member of the British Medical Association, serving as honorary secretary of the Glasgow and West of Scotland Branch from 1901 to 1903, and as a member of the Branch Council in 1909. In 1904 he was elected vice-chairman of the Glasgow Southern Division, becoming its chairman in 1905, and a member of the Executive Committee from 1906 to 1908, and from 1910 to 1911. He served on the Council of the Association from 1903 to 1904, and from 1907 to 1908. He was also a member, and sometime president, of the Glasgow Southern Medical Society and the Glasgow Royal Medico-Chirurgical Society.

The following well-known foreign medical men have recently died: Professor RICHARD LUMPE, a prominent obstetrician and gynaecologist of Salzburg, aged 75; Dr. SOMA BECK, professor of dermatology at the Elizabeth University of Fünfkirchen, Hungary; and Dr. WILFRED MASON BARTON, professor of medicine and applied therapeutics at Georgetown University School of Medicine, aged 58.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has been in committee on the Finance Bill this week, and has discussed the Estimates for the Dominions Office and Colonial Office. The Land Drainage Bill was read a second time. The House of Lords has insisted upon its amendments to the Coal Mines Bill, including one to permit a ninety-hour working fortnight in mines.

Mental Treatment Bill.

The Mental Treatment Bill was before the House of Commons for the last time on June 20th, when the House considered the changes made by the Lords when the bill was returned there recently from the Commons. The House of Commons now accepted a drafting amendment made by the Lords in Clause 5, dealing with the issue of a free copy of an order or recommendation to the person detained under it or to his representative. Miss LAWRENCE, for the Minister of Health, then moved that the Commons agree with the Lords' decision to delete the new clause which provides for an audit, under the Board of Control, of the accounts of licensed houses. She reminded the House that this clause was not part of the original bill, which did not propose to deal with the perplexing and controversial topic of licensed houses. Dr. Fremantle had brought forward the new clause at the wish of Sir Boyd Merriman, and the Government had agreed to it in committee, but did not feel that it was of importance. It dealt with the fringe of a subject which future Parliaments would deal with fully and properly. The Government did not feel justified in endangering the bill for it.

Sir BOYD MERRIMAN pointed out that the bill provided for the reception of patients into licensed houses. The Royal Commission had recommended that there should be more of these houses. He did not oppose Miss Lawrence's proposal.

Mr. GOULD asked the House to insist on the amendment. He asserted that there were many private institutions in which excessive charges were made. He had heard of charges of £20 a week.

Dr. MORRIS-JONES said the new clause under discussion would not make any difference to the charges of these private institutions.

The House then agreed with the Lords that the audit clause should be deleted. The bill was then returned to the Lords to await the Royal assent.

The Workmen's Compensation (Silicosis) Bill.

This bill, which has passed the House of Lords, received a second reading in the House of Commons on June 20th. Mr. SHORT, in moving the second reading, said the bill was to amend the provisions of Section 47 of the Workmen's Compensation Act, 1925, which gave power to the Secretary of State to make schemes enabling employers to pay compensation to workpeople who contracted the disease of silicosis caused by silica dust. The bill provided for the introduction of improved medical arrangements for the diagnosis and certification of cases of silicosis, and extended the provisions of Section 47 of the Act of 1925 to fibrosis of the lungs caused by asbestos dust, now known as asbestosis. The diagnosis of silicosis had been found to be very difficult, requiring special skill and the latest scientific knowledge and appliances in connexion with radiography and so forth. To meet this difficulty, Section 47 of the Act of 1925 made provision for schemes for the appointment of medical boards consisting of whole-time medical officers, but no provision for the setting up of any special fund out of which these whole-time medical officers can be paid. In the refractories and sandstone industries a general trade compensation fund has been created, to which salaries might be charged, and a medical board had been instituted. In 1928 Lord Brentford launched the Various Industries Silicosis Scheme, but no compensation fund had been created by any of the industries covered by that scheme. The medical examination and certification in the case of silicosis depended upon the ordinary medical machinery. The certifying factory surgeon was the responsible person, and there was a right of appeal to the medical referees under the Workmen's Compensation Act. This system had been found to be inadequate as regards the diagnosis of silicosis. The certifying factory surgeon was not an expert, and had not at his disposal radiographic and other resources. Consequently it had been found necessary to limit the scheme to death and total disablement, excluding partial disablement due to silicosis. When the bill had been passed and the necessary medical organization established the Home Secretary intended to proceed with an amending order to remove these anomalies. The first object of the bill was to secure uniform and effective arrangments for diagnosis and certification of silicosis in all cases, and to provide for the payment of compensation in all the industries concerned in respect of partial incapacity. It was proposed that the medical arrangements to be embodied in the general scheme should be based on the recommendations of the Silicosis Medical Arrangements Committee, which consisted of Dr. Briggs, the senior medical inspector of factories, Professor Arthur Hall of Sheffield, and Dr. Coutts of the Ministry of Health. They recommended that medical boards appointed by the Secretary of State, consisting of at least two specially qualified whole-time officers, should form the basis of the medical arrangements, with panels set up at different centres. The work should be co-ordinated by a chief medical officer, with a central bureau in Sheffield. The Home Secretary proposed, with the consent of parties interested in the refractory and sandstone industries scheme, to convert the existing medical board into a national board.

Dr. VERNON DAVIES asked if these boards would be directly under the Factory Department of the Home Office.

Mr. SHORT said that he understood they would be under the Home Office. He detailed the provision made for a medical expenses fund, maintained by fees. The Departmental Committee had stressed the need for initial and periodic medical examinations of workers. The Potteries Workmen's Compensation Committee had arrived at a similar conclusion, and said that such examinations tended to the elimination of pulmonary tuberculosis and to the detection of early silicosis. Very striking evidence had also been given by Dr. Sutherland of Sheffield. There were possibly 60,000 or 70,000 workers affected by the bill. Periodic examinations would be made only as prescribed under the scheme and in processes where they were really necessary. The clause extending the power of making compensation schemes to industries involving exposure to asbestos dust on the lungs was in accord with a recent wide inquiry by Dr. Merewether and Mr. C. W. Price, H.M. inspectors of factories. They concluded that the risk of an asbestos worker contracting fibrosis of the lungs was large.

Mr. DOUGLAS HACKING said that when at the Home Office he had visited Sheffield and Stoke. In some of the well-managed factories every precaution was taken so that the siliceous dust could not get into the lungs of the workmen. In Sheffield they had abrasive wheels which did not contain silica. The dust from them did not affect the lungs in the same way as dust from silica wheels. He believed a great deal could still be done towards preventing this disease, and he begged the Government to consider whether it could not press certain employers to have these safety devices installed in their factories. He believed that to conquer the disease more than 100 doctors would be required to carry through 70,000 examinations a year—not ordinary doctors, but specialists. The Treasury should give a substantial grant to the industry for this expense.

Dr. VERNON DAVIES welcomed the bill. He said it was a skeleton, and its success must depend on the scheme to be prepared by the Home Secretary. He was glad the panel of doctors would be under the Home Secretary. The silicosis diseases were not incurable in the early stages. The health was slightly deteriorated, but if the patient was removed from the industry in time there was practically no detrimental effect. If such men subsequently developed chronic bronchitis they might claim for silicosis, and trouble would result unless there was absolute confidence in the medical men who examined these cases. One result, particularly in the worst industries, would be that only first-class lives would be admitted. Therefore it was essential that the medical men should be absolutely above suspicion, and that the medical boards should be absolutely under the Home Secretary, with a Government medical service. It would not require 100 doctors. The most serious cases would be examined first, and those where the risk was greatest. Six or seven medical boards would be needed. It would not follow that every miner who had a trace of silica in his lungs would be scheduled for compensation.

Mr. HARDIE declared that silica dust must be prevented from reaching people living near the works. It affected the women and children in Staffordshire.

The bill was read a second time without a division.

Cancer.

On June 18th Miss LAWRENCE, replying to Mr. Mills, said that no financial assistance was provided from the Exchequer for the provision of beds for the special treatment of cancer, but Parliament had voted £100,000 towards the provision of radium. The figure of 550 beds mentioned in the hon. member's question was presumably an estimate of the number of beds available only in those hospitals devoted wholly or mainly to the treatment of cancer, but it would be understood that the majority of cancer patients who were treated in hospital were admitted to general or public authorities' hospitals.

Mr. MILLS asked if Miss Lawrence was aware that the vast majority of these beds in hospitals at the moment were still subject to a means test, under which something had to be paid, and that consequently thousands of cases had to go by default for lack of necessary help by the Government.

Dr. VERNON DAVIES asked if Miss Lawrence was aware that at no hospital in the kingdom was a cancer case refused admission if any treatment could be given for its good.

Earl WINTERTON asked the hon. lady if she would give a reply to the monstrous charge made by Mr. Mills that cases were refused by voluntary hospitals on a means test. As chairman of a hospital he greatly resented that suggestion.

Miss LAWRENCE replied that she thought the only way in which she could reply to an allegation of that kind was by answering a question which might ask for further details and in which she might be asked to investigate.

Mr. MCSHANE asked if it was not the case that numbers of people who knew that they would be expected to pay something when they got in were, in that sense, deterred from entering a hospital.

Viscountess ASTOR asked if it was not the fact that a great many people were willing to pay for treatment if they could get into a hospital. It was not that hospitals would not take them; a great many people were willing to pay, but could not get any hospital because there were not the hospitals. No answer was given to the last two questions.

Hours of Shop Assistants.

The Select Committee on the hours of shop assistants heard evidence, on June 18th, from Mr. J. R. LESLIE, general secretary of the National Amalgamated Union of Shop Assistants, Warehousemen, and Clerks. He said that so far there had been only two measures limiting the working hours of assistants. Long hours behind the counter, worked often in a vitiated atmosphere, had a detrimental effect on the health of those employed. In the recent debate on shop hours in the House of Commons Dr. Bentham, speaking as a medical practitioner, declared that the health of shop assistants compared extremely badly with that of people in almost every other trade. The Shop Acts made no provision for sanitation, ventilation, or other health safeguards, as did the Factory and Workshops Acts. In large numbers of cases shop assistants stood almost elbow to elbow behind their counters. Ventilation on any scientific plan was paid to keeping existent, and in thousands of shops no regard was often non-a reasonable temperature. During the winter months the sick benefit paid by the union's approved society to its members was greatly increased, and was traceable in great part to the unheated shops. In February of last year, during an extremely cold spell of weather, the sickness ratio rose to the highest peak which their approved society had experienced. In a large number of shops there were no sanitary conveniences at all. Women were sometimes called on to lift weights which were liable to cause injury. He asked that the Factory and Workshops Act should be extended to include shops, warehouses, and offices, and that the standard set by the Home Office for sanitary conveniences should apply to shops.

The committee adjourned.

Indian Medical Degrees.

Mr. BENN told Major Pole, on June 18th, that he had not yet received the view of the Government of India in regard to the proposal to revive the competitive examinations for admission to the Indian Medical Service, but had ascertained that the Government did not propose to introduce legislation for the setting up of an All-India Medical Council during the next session, as it would be a very short one. The Government of India had, however, convened a conference, which Ministers in charge of medical administration, heads of medical departments, and representatives of medical faculties of universities have been invited to attend, that the principles of the proposed legislation might be settled. The agreement of the Provincial Governments would then be invited. The conference would meet on June 23rd, and would discuss all matters arising out of the temporary suspension of the recognition of Indian medical degrees by the General Medical Council.

Mr. BENN, replying on June 23rd to Mr. Freeman, said that the intention of the Government of India was to establish an All-India Medical Council, which would regulate the recognition of medical qualifications in India. Dr. VERNON DAVIES asked how any decision of the Indian Government to consider the formation of an Indian Medical Council could help Indian gentlemen who might desire to practise in this country. Dr. BENN replied that he would require notice of special points. Dr. MORRIS-JONES asked Mr. Benn whether he had been in consultation with the General Medical Council. Mr. BENN: The whole matter arose in connexion with the General Medical Council.

Consumption of Opium in British India.—On June 18th Mr. BENN informed Major Pole that he had not yet received a report on the results of the recent conference called by the Government of India to discuss methods of dealing with the high consumption of opium in certain areas in British India.

Notes in Brief.

On March 31st, 1930, 1,034,368 persons over the age of 65 were in receipt of old age pensions. Of these, it was estimated that 355,000 were still employed.

Ten inspectors of physical training are employed under the Board of Education. During the year ended December 31st last they paid 561 visits to elementary schools, 357 to secondary schools, and 137 to training colleges.

The average sick leave of sorting assistants in the Post Office during 1928 and 1929 was 11.5 days and 14.5 days respectively. The average sick leave of supervisors of sorting assistants was 13.7 days in 1928 and 22.1 days in 1929.

On June 24th Mr. Clynes told Major Nathan that officers of the Metropolitan Police did not carry first-aid appliances for use in cases of necessity. They were expected to improvise from any material available.

The Services.

HONORARY PHYSICIAN AND HONORARY SURGEON TO THE KING.

Major-General J. W. D. MEGAW, C.I.E., I.M.S., honorary surgeon to the Viceroy of India, has been appointed honorary physician to the King, vice Major-General A. Hooton, C.I.E., I.M.S. (ret.). Lieut.-Colonel F. D. G. Howell, D.S.O., M.C., R.A.M.C., has been appointed honorary surgeon to the King, and to be promoted to brevet-colonel, vice Major-General D. Harvey, C.B., C.M.G., C.B.E., late R.A.M.C. (ret.).

INDIAN MEDICAL SERVICE.

Annual Dinner.

The annual London dinner of the Indian Medical Service was held at the Trocadero Restaurant on June 18th. The chair was taken by Major-General G. Tate in the absence through illness of Major-General F. H. G. Hutchinson. The guests were Sir Harry G. Waters, Mr. F. H. Brown, Dr. N. G. Horner, Editor of the *British Medical Journal*, Dr. E. C. Morland of the *Lancet*, and Air Vice-Marshal Sir David Munro, together with the five I.M.S. officers now on probation at the Royal Army Medical College, Millbank.

The chairman, in proposing the toast of "The Indian Medical Service," said that they were awaiting the recommendations of the Simon Commission with reasonable confidence. Though some of the glory of the I.M.S. had departed its sun had by no means set; it still offered a fine career, and the research opportunities in India were unrivalled in any other part of the world. Lieut.-Colonel J. K. S. Fleming, in proposing "The Health of the Chairman," spoke of the changing conditions in India, and regretted that the I.M.S. had become the plaything of the political world. It would, he said, be better for everyone if it were recognized that the medical service in India had nothing whatever to do with politics. The health of the honorary secretaries, Colonel T. A. Granger and Sir T. Carey Evans, was proposed by Lieut.-Colonel D. G. Crawford, and compliments were paid also to Lieut.-Colonel Fleming for his work in Simla on behalf of these successful and enjoyable annual dinners.

The following is a list of the officers present at the dinner:

Major-Generals: R. W. Anthony, C.I.E., A. A. Gibbs, K.H.P., G. F. A. Harris, C.S.I., A. Hooton, C.I.E., Sir Leonard Rogers, C.I.E., F.R.S., Sir T. H. Symons, K.B.E., G. Tate, C.I.E., K.H.S.

Colonels: H. Ainsworth, J. Anderson, C.I.E., R. F. Baird, J. Fullerton, J. D. Graham, C.I.E., T. A. Granger, C.I.E., C. R. M. Green, A. J. Macnab, C.B., C.M.G., F. P. Mackie, O.B.E., F.R.S., W. G. P. Alpin, O.B.E.,

Lieut.-Colonels: A. W. Alcock, C.I.E., F.R.S., W. V. Coppinger, D.S.O., A. G. Coullie, H. E. Brown, A. Buchanan, W. V. Coppinger, D.S.O., A. G. Coullie, D. G. Crawford, J. M. Crawford, O.B.E., K.H.S., A. B. Fry, Hamilton, C.B.E., G. F. Graham, A. E. Griesewood, A. F. Hamilton, J. A. Hamilton, D.S.O., W. G. Hamilton, B. Higham, E. V. Hugo, C.M.G., J. B. Hunter Dalzell, O.B.E., S. P. James, H. Kirkpatrick, E. C. G. Maddock, C.I.E., F. O. N. Mell, C.I.E., A. Miller, T. R. Mulroney, R. A. Needham, C.I.E., O.B.E., F. O'Kinealy, C.V.O., C.I.E., C. H. Reinhold, E. R. Rost, A. N. Stokes, A. J. H. Russell, C.B.E., G. M. C. Sykes, D.S.O., C. Thomson, T. A. Thomson, Ashton Street, W. A. Sykes, C.M.G., R. Steen, G. Sloane Wilson, O.B.E., W. H. Thornhill, E. L. Ward, C.B.E., D. Warliker, C. M. D. Clyde, Sir T. Carey Evans, M.C., N. H. Hume, Clive Newcombe, J. M. Shah.

Majors: R. T. Advani, S. C. Alagappam, F. J. Anderson, M.C., J. R. Kataria, R. MacRobert, Percy Devonport, S. D. S. Greval, H. M. Strickland, F. H. White.

Captains: M. P. Atkinson, R. N. Bhandari, J. Carrey, H. A. Culhane, Captain J. McM. Wilder, Lieutenant F. H. A. L. Davidson, Lieutenant R. T. Hicks.

Officers on Probation: Captain E. G. Hurdwood, Captain M. H. Wace,

DEATHS IN THE SERVICES.

Lieut.-Colonel Frederick William Gee, C.I.E., Bengal Medical Service (ret.), of Westmead, Cookham, Berks, died in the Royal Northern Hospital, London, after an operation, on June 3rd, aged 67. He was born on March 11th, 1863, the son of the Rev. William Gee, vicar of East Coker, Somerset, was educated at Sherborne and at University College, London, and took the M.R.C.S. and L.S.A. in 1886. Entering the I.M.S. as surgeon on B.S.Lond. in 1887. Entering the I.M.S. as surgeon on March 31st, 1888, he became lieutenant-colonel after twenty years' service, was placed on the selected list for promotion on April 1st, 1916, and retired on August 5th, 1920. His whole service was spent in military employ, chiefly in the Bengal Cavalry. He served on the North-West Frontier of India in the Chitral campaign of 1895, took part in the relief of Chitral, and received the frontier medal with a clasp; in China, 1900, medal; in East Africa, in Somaliland, in 1903-4, mentioned in dispatches in the *London Gazette* of September 2nd, 1904, medal with clasp; and in the war of 1914-18, when he was mentioned in dispatches four times, in the *London Gazette* of August 15th, 1917, March 12th, 1918, August 17th, 1918, and February 21st,

1919, and, in addition to the medals, received the C.I.E. on June 3rd, 1915. He received a good service pension on August 18th, 1928. He married Jessie Elizabeth, daughter of John Graves of Southgate, and leaves a son and two daughters.

Lieut.-Colonel Narendra Prasanna Sinha, Bengal Medical Service (ret.), died on February 14th, aged 71. He was born on September 30th, 1858, and was educated in the Calcutta Medical College. After taking his degree there, he was appointed a civil assistant surgeon in Bengal in 1881; but a year later came to England, where he took the M.R.C.S. in 1882 and the M.R.C.P.Lond. in 1883, and passed into the I.M.S., being commissioned as surgeon on April 1st, 1886. He became surgeon major after twelve years' service, and retired on June 1st, 1904. After a few years' military service he got civil employ in Bengal, and was civil surgeon of Rangpur at the time of his retirement. After leaving the service he was for several years in practice at Ealing. In 1914, when the war began, he returned to India, and rejoined for service on January 30th, 1915. During the war he held various civil appointments in Bengal, and after it was ended continued to serve as police surgeon, Calcutta, up to January 10th, 1922. He was promoted to lieutenant-colonel from February 5th, 1917. He served in the Burmese campaigns from 1885 to 1889, receiving the medal with two clasps. He was a brother of Lord Sinha, late governor of Bihar and Orissa, the first, and so far the only, Indian to receive a peerage and to hold a provincial governorship.

Major Ian Paterson, R.A.M.C. (ret.), of Ardru, Onich, Inverness-shire, died there on June 7th, aged 69. He was born in Edinburgh on June 6th, 1861, was educated at the University in that city, and graduated as M.B. and C.M. in 1885. Entering the Army as surgeon on July 27th, 1887, he became major on July 27th, 1899, was on temporary half-pay on account of ill health from September 26th, 1902, to April 26th, 1903, and retired on July 27th, 1907. He served on the North-West Frontier of India in the Chitral campaign of 1895, with the relief force, receiving the frontier medal with a clasp; and in the South African war from 1899 to 1901, when he took part in the relief of Ladysmith, including the actions of Spion Kop, Tugela Heights, Vaal Kraietz, and Pieter's Hill, and in operations in Natal, including the action at Laing's Nek, and in the Transvaal, the Orange River Colony, and Cape Colony; and received the Queen's medal with seven clasps. He was also re-employed in the war of 1914–18, from August 5th, 1914.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE Vice-Chancellor announces that the Downing Professorship of Medicine is vacant by the death of Dr. J. B. Bradbury. Dr. L. E. Shore has been reappointed university lecturer in physiology for three years, and Mr. J. E. Purvis university lecturer in chemistry and physics in their relation to hygiene and preventive medicine for the same period.

The Vice-Chancellor gives notice that a congregation will be held on Saturday, August 2nd, at 2 p.m., for the conferment of medical and surgical degrees.

At a congregation held on June 21st the following medical degrees were conferred:

M.D.—L. S. Penrose, J. B. Ellison, P. M. D'A. Hart, T. F. Anderson, G. T. Calthrop.

M.B., B.Chir.—L. A. Richardson, W. H. Simonds.

M.B.—W. J. G. Drake-Lee.

UNIVERSITY OF LONDON.

THE Rev. J. SCOTT LIDGETT, D.D., has been elected Vice-Chancellor for 1930–31, in succession to Sir Gregory Foster, whose term of office expires on August 31st. Mr. J. L. S. Hatton, principal of the East London College, will succeed Dr. Scott Lidgett as Deputy Vice-Chancellor.

Dr. C. Cyril Okell has been appointed to the University Chair of Bacteriology at University College Hospital Medical School.

The degree of D.Sc. in Chemistry has been conferred upon Mr. Harold Burton, an internal student of Guy's Hospital Medical School.

UNIVERSITY COLLEGE.

Mr. R. K. Cannan, M.Sc., has resigned his lectureship in biochemistry on his appointment to the Chair of Chemistry in New York University. Mr. G. F. Marrian, M.Sc., has been appointed lecturer.

In the list of successful candidates for the Third M.B., B.S., published in our issue of June 14th (p. 1117), the sign indicating that Ursula Shelley had gained distinction in Forensic Medicine was accidentally omitted in the course of printing.

UNIVERSITY OF WALES.

THE following scholarships will be awarded in the session 1930-31, provided suitable candidates are forthcoming: (1) Cecil Prosser Research Scholarship (£250), for research in the department of tuberculosis; (2) Mrs. John Nixon Scholarship (£150), for research in the department of medicine and medical pathology; (3) Lord Merthyr Research Scholarship (£200), for research in the department of surgery; (4) Ewen Maclean Research Scholarship (£150), for research in the department of obstetrics and gynæcology. Full particulars and forms of application may be obtained from the Registrar, University Registry, Cathays Park, Cardiff.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THE Victoria Jubilee Cullen Prize for 1930 has been awarded equally between Professor George M. Robertson, M.D., F.R.C.P., Physician-Superintendent of the Royal Hospital, Morningside, Edinburgh, and Sir Andrew Balfour, K.C.M.G., M.D., F.R.C.P., Director of the London School of Hygiene and Tropical Medicine. The value of the prize is £100.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—F. R. Crookes, H. J. Hale, J. Irger, C. Seeley.

MEDICINE.—G. T. W. Cashell, L. P. Clarke, F. R. Crookes, H. G. Edmunds, I. F. W. Edwards, H. Glynn, H. J. Hale, E. Lethem, E. H. W. Lyle, A. W. B. Wiggins.

FORENSIC MEDICINE.—F. R. Crookes, R. P. Davies, H. J. Hale, J. E. R. Heppoletto, K. V. B. Pillai, E. M. M. Shaw, G. Wilsker

MIDWIFERY.—V. J. H. Coidan, F. R. Crookes, H. J. Hale, K. V. B. Pillai, E. M. M. Shaw, I. J. Todd-Naylor, I. M. Williams.

The diploma of the Society has been granted to Messrs. L. P. Clarke, V. J. H. Coidan, F. R. Crookes, I. F. W. Edwards, H. J. Hale, E. Lethem, E. M. M. Shaw, and A. W. B. Wiggins.

Medical News.

H.R.H. PRINCESS MARY COUNTESS OF HAREWOOD will open the first section of the new Queen Charlotte's Hospital in Goldhawk Road, Hammersmith, at 2.45 p.m. on Thursday, July 10th.

AN intensive course in radiotherapy will be held at the National Post-Graduate School of Radiotherapy (the Mount Vernon Hospital and Radium Institute), Riding House Street, London, W.1, commencing Monday, October 6th. Full particulars will be announced later. Applications for copies of the syllabus may be made at once, and these will be forwarded as soon as available. The dean (Sir Cuthbert Wallace) will be glad to see prospective entrants by appointment. The course will be repeated on subsequent dates.

THE Fellowship of Medicine and Post-Graduate Medical Association announces two special M.R.C.P. lectures: the first on July 1st at 8.30 p.m. at 11, Chandos Street, W.1, by Dr. W. J. Adie on diseases of the nervous system, the second on July 4th at 8.30 p.m. at 10, Bedford Square, by Dr. A. Knyvett Gordon on diagnosis and treatment of certain bacteriological infections, followed by a laboratory demonstration. Fees payable at lecture rooms. Two free demonstrations will be given during the week, both on July 1st. The first is at 9 a.m. in the out-patient department of the Royal Ear Hospital, Huntley Street, by Mr. Herbert Tilley, and the second at 2 p.m. in the out-patient department of the Hospital for Epilepsy and Paralysis, Maida Vale, by Dr. D. McAlpine. A special course in proctology, with demonstrations, operations, and lectures, will take place at St. Mark's Hospital from June 30th to July 5th, occupying the whole of each day; fee £3 3s. A short course of demonstrations at various hospitals has been arranged in connexion with Baby Week from June 30th to July 5th. The fee is 10s., and a few vacancies will be reserved for graduates other than medical officers of health. A course in diseases of infants will be given from July 21st to August 2nd at the Infants Hospital; it will occupy each afternoon and include some special visits. Copies of all syllabuses and tickets of admission may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1, to which all fees are payable.

A POST-GRADUATE course in oto-rhino-laryngology will be held at Strasbourg from July 15th to 27th, under the direction of Professor Canuyt. The fee is 400 francs.

THE second international congress of comparative pathology will be held at the Faculty of Medicine in Paris, from October 14th to 18th, 1931, during the French colonial exhibition. Professor Achard will be the president, and the subjects to be discussed include tuberculosis, cancer, psittacosis, the ultra-viruses, undulant and *abortus* fevers, anaphylaxis, and milk. Further information may be obtained from the general secretary, Dr. Grollet, 7, rue Gustave Nadaud, Paris, 26e.

DR. G. B. HILLMAN has been adopted by the Wakefield Conservative Association as the prospective parliamentary candidate for Wakefield. He has been a member of the Wakefield City Council since 1926, and was mayor in 1928.

THE ninth session of the International Association for the Protection of Childhood will be held at Liège, from July 31st to August 4th, on the occasion of the celebration of the centenary of the independence of Belgium. The following subjects, among others, will be discussed: tuberculosis in school children, introduced by Dr. Armand-Delille; protection of children of pre-school age (3 to 6 years), introduced by Dr. Rovèche; the rational examination of school children, introduced by Drs. Lauter, Grosset, Chailly-Bert, and Simon; and the physiology of digestion and the nutrition of the infant, introduced by Professor Rohmer. Further information can be obtained from the general secretary of the association, 67, Avenue de la Toison d'Or, Brussels.

THE twenty-third "Voyage d'Etudes Médicales," arranged for doctors in practice and for medical students who have completed their studies, will take place from September 1st to 15th, under the direction of Professor Villaret, of the Faculty of Medicine, Paris; of Professor Santenoise, of the Faculty of Medicine, Nancy; and of Dr. Blum, of the Faculty of Medicine, Strasbourg. Starting at Nancy and ending at Vittel, the tour will embrace the mineral water and climatic stations of Alsace, Jura, and the Vosges. The inclusive charge covering hotels, cars, tips, etc., is 1,100 francs. Reductions of 50 per cent. will be allowed on French railways for the outward and return journeys. Details of the programme and full particulars may be obtained from the office of the Federation of the Health Resorts of France, Tavistock House North, W.C.1.

IN the preliminary programme of the seventh international birth control conference, to be held in Zürich from September 1st to 5th, the following subjects are announced for discussion: birth control in relation to the health and economic conditions of men, women, and children; the general application of the occlusive pessary and other extra- and intra-uterine contraceptive appliances; composition and use of chemical contraceptives; physiological methods of contraception; new methods and experiments, with special reference to serums, spermatoxins, and the use of *x* rays and radium. The aim of the conference is to bring together the directors and workers of the various birth control clinics throughout Europe and the United States, and attendance will be by invitation only. Particulars may be obtained from Mrs. Janet Chance, c/o A. S. Cobden, Esq., 10, Adelphi Terrace, W.C.2.

THE publicity department of the Harrogate Corporation has issued an attractively illustrated pamphlet concerning the amenities of this famous spa. Condensed information about baths and pump rooms is supplied for invalids; but the town with its exhilarating air and its devotion to flowers and music is commended both as a pleasure resort and as a permanent residence. More than a hundred different methods of treatment are now employed at the bathing establishments. A separate booklet containing full particulars of the waters and of the treatments available may be obtained free of cost from the manager of the Baths Department, Harrogate.

THE issue of *Nature* for June 21st publishes, as a supplement, an abridged version of the six Hunterian Lectures given before the Royal College of Surgeons of England last month, by Sir Arthur Keith, on "Recent discoveries of fossil man."

A FURTHER programme of conducted tours has been arranged for July and August by King Edward's Hospital Fund. On July 4th at 5 p.m., Mr. Lawrence Tanner will take a party over Westminster Abbey, including parts of the building not ordinarily on view. On the afternoon of July 16th a visit will be made to the London Air Park at Hanworth, and on August 13th and 20th and September 3rd parties will be taken over the Tower of London, under the guidance of Mr. Walter Bell. Tickets (price 10s. for each event) can be obtained from King Edward's Hospital Fund for London, 7, Ash-cook, E.C.4.

THE late Lord Dewar has bequeathed £5,000 to St. Paul's Hospital and £2,000 each to Charing Cross Hospital and St. George's Hospital.

DR. GEORGE E. DE SCHWEINITZ, professor of ophthalmology in the University of Pennsylvania Graduate School of Medicine, has been awarded the Leslie Dana medal for prevention of blindness for 1930.

PROFESSOR L. T. HOGBEN of the University of Capetown has accepted the new chair of social biology at the London School of Economics (University of London). This appointment is a striking recognition of the importance of biological science in the study of modern social problems.

DR. F. J. WALDO, coroner for the City of London and Borough of Southwark, at an inquest held on June 12th on a case of death under chloroform and other anaesthesia, said that this was the second case he had investigated recently in which death had occurred under this anaesthetic mixture before the operation had actually started.

A FURTHER series of brochures—Nos. 195 to 205—has been issued by the International Labour Office in continuance of its series entitled "Occupation and Health." Their subjects are: dyeing; effort (strain); electrical apparatus; electroplating; emetine, enamels, and enamelling; ethylene and its derivatives; forges, ironworks; hor-chair, bristles, and hair; glove manufacture; dock labourers; dusts, fumes, and smoke; and dyes. They may be obtained from the London office of this organization, 12, Victoria Street, S.W.1.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association are *MUSEUM 9961, 9962, 9963*, and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963*, and *9964* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medsecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF PRURITUS ANI.

DR. D. M. MACDONALD (Armside) writes: In reply to "Cerona's" inquiry (June 7th, p. 1020), I would suggest that he takes each night one hour before bedtime 1·8 to 1·4 grain of calomel, a dose that stops short of acting on the bowels. At the same time he should take 5 grains of sodium bicarbonate, which oxidizes the mercurial salt and converts it into a potent oxide. The fact that the pruritus comes on after the patient has been in bed, a fairly common feature, led me some years ago to the conclusion that the cause of the complaint is some chemical interference and change in the biliary secretion. The above treatment, carried out for two or three weeks, is, in the majority of cases, most effectual. In cases which resist this treatment I find that forcible stretching of the sphincter under a general anaesthetic is usually effective.

DR. J. P. SCATCHARD (Tadcaster) writes: I can strongly recommend the subcutaneous injection of anaesthesin in the form of azoule solution, "A.B.A." (Allen and Hanburys). It can be given painlessly, and does not cause any after-discomfort. The method was described in a paper by W. B. Gabriel (*British Medical Journal*, June 15th, 1929, p. 1070). Along with it a calamine lotion may be used after evacuation.

"SEPTUAGENARIAN" writes from Nottingham: I would suggest to "Cerona" and other sufferers that they should try the simple remedy of washing the anal region every night, just before going to bed, with soap and water, drying with a soft cloth. In my own case this simple treatment has been perfectly satisfactory.

INCOME TAX.

Car Transactions.

"M. B." had a car, the value of which appeared as £235 "in the previous year's Profit and Loss Account, under Stock Account." He has sold it for £90, and purchased a new car for £390 in the present financial year. What can he claim?

* * The transaction will affect the tax payable for next financial year, when he can claim (1) obsolescence allowances £235—£90=£145, and (2) depreciation allowance at, say, 20 per cent. on £390, say, £78.

Cash Receipts Basis.

"T. D. R." started practice in 1924, and his returns have hitherto been made (and accepted) on the basis of cash receipts. The inspector of taxes now objects to that basis, and for the current year has added £50 to the cash profit figures as his estimate of the increase in the amount of fees outstanding.

*** There is no legal justification for the adoption of the cash basis; its acceptance by the Inland Revenue is the result of a recognition of the fact that the value of a medical practitioner's debts is difficult to estimate, and also of the consideration that in a normal case the amount of the cash receipts over a period of years will approximate closely to the value of the bookings over the same period. But the latter consideration does not apply if the practice is growing; in that event the amount of the cash receipts lags behind the bookings of the same years, and a return based on cash receipts therefore is less than the true liability. If that is the case with "W. T. R.'s" practice, his only remedy is to compute the value of the book debts outstanding at the beginning and end of the year as best he can; if the income is not expanding, he might point out to the inspector that there seems to be no justification for his departure from a well-established practice of assessment in the case of professional profits.

Retirement of Partner: Succession.

B and C have been in partnership since June, 1929, on a three-fifths and two-fifths basis; prior to that A was also a partner in the firm, the basis of division being two-fifths, two-fifths, and one-fifth. A continues to draw cash representing two-fifths of the receipts from work done before June, 1929. How should B and C be assessed?

*** As from June, 1929, A ceased to be liable in respect of his drawings from the practice, those drawings representing the cash accumulations of earnings over periods for which he had accounted for his income tax liability. Conversely, as from that date B and C are entitled to the whole of the earnings of the practice, and must account for tax accordingly, and not merely on that portion of their earnings which reaches them in cash. Their liability can be computed in one of two ways—either on the basis of the value of the bookings or on the basis of the total cash received—but in neither case can A be charged on his cash receipts. B and C will be paying tax on income earned but not received, but that is in accordance with the income tax rules.

LETTERS, NOTES, ETC.

PATENTING OF MEDICAL INVENTIONS.

MR. A. HOME-MORTON, general manager of the Hoffmann-La Roche Chemical Works Ltd., writes: In his lecture on "Fine chemicals," reported in the *British Medical Journal* (May 24th, p. 957), Mr. Frank Lee Pyman, F.R.S., referred to "the brilliant work of Harington and Barger in determining the constitution and the synthesis of thyroxine," and the monopoly which a Swiss firm had acquired by securing British patent No. 318582 for an improvement on the novel, but unpatented, method of synthesizing thyroxine adopted by Harington and Barger. I am authorized to make the following statement on behalf of Messrs. F. Hoffmann-La Roche and Co., A.G., of the "Roche" Research Laboratories, Basle, Switzerland, the holders of the patent in question. They write: "Apart from the question of the actual value of the process covered by our patent, it is quite certain that, compared with Harington's fundamental invention, it is of minor importance. By taking out this patent we aspired to no monopoly. We merely wished to manifest to the outer world that our laboratories had been successful in improving the method. In order, however, to avoid any misconstruction of our intentions, and in view of Pyman's arguments, we have decided to relinquish our claim to the patent, and thus to allow our process to become general property." I should be grateful if you would give this friendly and open-handed gesture the publicity it deserves.

BRITISH-MADE INSTRUMENTS.

SIR JOHN CORCORAN, director of the National Union of Manufacturers, writes: In your issue of May 3rd you were good enough to publish an appeal from this Union to the committees of our large voluntary hospitals to set an example to similar bodies by equipping the institutions under their control with instruments of British manufacture. It will not be denied that by following this course at a time when we have over 1,700,000 unemployed, and when so many of our factories, including those engaged in the production of surgical instruments, are sorely in need of work, they will be acting in accordance with the wishes of the vast majority of their subscribers. I am moved to repeat my appeal because I have recently seen a letter from a well-known hospital asking for prices of hospital equipment in which it was expressly stated that the articles need *not necessarily* be of British make, and by a statement in the public press that two of the experts from one of the best-known metropolitan hospitals had proceeded to the Continent to select *x*-ray apparatus. No one disputes that our hospitals must be administered in the interest of the patients, and that if instruments of a suitable standard could not be purchased in this country they won't have to be obtained elsewhere; but where—as in the case of *x*-ray apparatus—the reputation of British manufacturers is second to none, it is surely desirable that hospital experts should thoroughly explore the possibilities of obtaining what they want in this country before proceeding abroad on tours of selection.

DANISH TREATMENT OF ITCH.

THE following is an abstract of a long report by Mr. G. E. SHAW, B.Sc. (Evans's Biological Institute, Runcorn), on this subject: (1) The only reference to a black form of sulphur is in *Thorpe's Dictionary of Applied Chemistry*, vol. v, p. 296, 1916 edition. Thorpe says that black amorphous sulphur may be prepared by heating sulphur with soda. It is highly improbable that sulphur is the black substance obtained by Dr. Ross (February 15th, p. 320). (2) Dr. A. Cannon does not state whether the 50 per cent. KOH is weight/volume or weight/weight, and I have taken it as the latter. (3) He makes no allowance for evaporation losses, which are bound to occur during a day's heating, even though this heating be "gentle." He also is rather indefinite as to what temperature should be considered as gentle. (4) In the method whereby KSH is first formed and then converted to K_2S, Dr. Cannon does not state whether the sulphur is then dissolved to the same amount as when KOH is used directly. I have, however, read this interpretation into his statement. (5) In using Mr. Cable's technique it is noticed that sometimes a thick crust forms, leaving a *deep* orange-yellow solution below. This has happened in my experiments, and the crust is obviously very largely sulphur. (6) Marcussen of Copenhagen frequently uses double the quantity of 50 per cent. KOH, and always obtains a clear solution. (7) In the original formula the proportions of potassium and sulphur are 40 to 100 weight/weight. In the K_2S solution the ratio is about 40 to 16 weight/weight. In the K_2S solution plus the full amount of sulphur the ratio would be 40 to 116 weight/weight. Where the amount of KOH solution is doubled the amount of sulphur in unit weight of product is of course halved. In those cases where a crust has been removed the decrease of sulphur per unit of weight is indefinitely lowered. (8) Notwithstanding the points raised in 7, the weight of product incorporated in the ointment does not seem to be changed. (9) Using the technique recommended by Cannon and heating on the steam bath to a temperature approximately 90° C., I found it impossible to make the full amount of sulphur dissolve in the specified quantity of KOH. It was possible to dissolve half the amount of sulphur with comparative ease. No blackening was noted, but a transparent *deep* orange-yellow solution was obtained. This solution mixed with and dissolved readily in water, giving a clear pale yellow solution. The sulphur added much in excess of the 50 per cent. would not go into solution on a water-bath, even on a day's heating. On allowing evaporation to take place and increasing heat gradually to maintain fluidity, practically the full amount of sulphur could be got into solution as a dark reddish-yellow solution. This product, however, precipitated sulphur on dilution with water. Using double the amount of KOH with the same amount of water, a satisfactory deep orange solution could be obtained which mixed readily with water. This product set to a solid on cooling. (10) The probable explanations of the "blackening" noted by Dr. Ross are: (*a*) that one of his chemicals contains metallic impurity; (*b*) that what he has actually observed is the dark reddish-orange colour described above. (11) A further experiment has indicated that a satisfactory reddish-orange solution may be obtained by dissolving the sulphur in K_2S solution prepared according to Dr. Cannon's instructions. A temperature of approximately 90° C. is adequate, but still about 60 per cent. of the total amount of sulphur can be made to dissolve.

DEVELOPMENT OF PHOTOGRAPHS.

THE second of a series of booklets published by Burroughs Wellcome and Co. under the title of "Photography Simplified" has just been issued; this deals with the question of development by the most scientific and safe method—the time and temperature method—as well as the relationship between exposure and development. The after-treatment of negatives by intensification or reduction is also described, the illustrations showing the difference between correct development, over- and under-development, and the improvement in faulty negatives which can be effected by using "tabloid" reducers or intensifiers. Notes are included on developers in relation to particular classes of work. To any reader mentioning this journal the booklet will be sent post free by Messrs. Burroughs Wellcome and Co., Snow Hill Buildings, E.C.1.

THE PETROL ENGINE.

A THIRD and revised edition of *The Petrol Engine*, containing many new illustrations, has been published in the Temple Series of Manuals for Motorists, price 3s. 6d. As already indicated in these columns, this popular handbook presupposes little mechanical knowledge, and covers a wide field from the petrol driven lawn mower to the latest type of aeroplane engine. The descriptions are concise, well arranged, and readable.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 40, 41, 44, 45, 46, 47, 48, 49, and 52 of our advertisement columns, and advertisements as to partnerships assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 291.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

574. **Anatoxin Prophylaxis in Diphtheria.**

J. LARDIER (*Thèse de Paris*, 1930, No. 22) states that although the value of immunization against diphtheria has been proved, the method is not infallible, any more than that of any other form of immunization. Faucial diphtheria occurring in children who have been given three injections of anatoxin presents the same clinical appearances as in those who have not been inoculated, and the prognosis is about the same as in the non-immunized, severe and complicated attacks occurring in about a third of the cases. Deaths and paralysis, however, are slightly less frequent in those who have been immunized. With rare exceptions serum treatment should be conducted in the usual way without taking any notice of the previous inoculation. Faucial diphtheria occurring in children who have been given only two injections of anatoxin is apparently identical with that occurring in children who have been given three injections. On the other hand, faucial diphtheria following a single injection of anatoxin appears to be more severe than in those who have had two or three injections, and possibly even more severe than in the non-immunized. Practitioners, therefore, while still in favouring the principle of active immunization, should be made to realize the relative frequency and occasional gravity of diphtheria in those who have been immunized.

575. R. CRUCHET (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, March 20th, 1930, p. 237) reports five cases of the occurrence of diphtheria in children inoculated with Ramon's anatoxin, and calls attention to certain possibilities of error, such as a leaky syringe, or an ill-fitting needle-mount. Further, many children are given insufficient doses of anatoxin. Among 365 children treated by the author only 242 had received three injections of anatoxin, while 58 had had two injections, and 68 had been given only one dose. After elimination of all sources of error, it is admitted by the advocates of all inoculated properly remain refractory to immunization; this prophylactic method that 4 or 5 per cent. of all small percentage accounts probably for the small number of cases of diphtheria which occur in patients who have received a full course of injections. In the majority of these cases, however, the disease runs a very mild course. Cruchet concludes that it is a mistake to regard anatoxin injections as useless. The statistics of the Bordeaux area show a reduction in the number of cases of diphtheria since the introduction of routine injections. He considers that intensive prophylaxis is indicated, three or even four injections being given at intervals of two weeks, or, better still, of three weeks. It has to be remembered that about 5 per cent. of cases remain refractory. When diphtheria occurs among those who have previously received anatoxin injections, these patients should be treated as if they had not had any prophylactic treatment.

576. **Measles and Tuberculosis**

P. NOBÉCOURT, R. LIÉGE, and A. HERR (*Arch. Méd. des Enf.*, February, 1930, p. 65) report that of 459 children admitted to the measles block of the Hôpital des Enfants Malades, Paris, during the first six months of 1929, 33 (7.18 per cent.) showed a positive skin reaction for tuberculosis during the course of the disease, though in only 4 of them had there been definite evidence of this disease before admission. The subsequent history of the rest, none of whom had shown any clinical symptoms of tuberculosis before their attack of measles, was as follows. In 10 cases measles pursued a normal course, 3 died from the usual complications of measles, 7 developed subacute pulmonary tuberculosis as a sequel of measles, and 2 of them died, the diagnosis being confirmed by necropsy; 2 had peritonitis in convalescence, and 2 meningitis. The authors conclude that tuberculosis has no definite influence on the course of measles, but measles has an unfavourable effect on the course of tuberculosis in some cases, though not in all. Measles may give rise to an acute and fatal pulmonary broncho-pneumonia of measles is particularly frequent in tuberculous children, and in such cases is usually fatal. On the other hand, tuberculosis is not a very common sequel of measles, since out of 459 cases of measles only 15 (3.48 per cent.) definitely developed tuberculosis. Moreover, only 62 per cent. of cases of tuberculous meningitis gave a recent history of an attack of measles. In some patients, before tuberculosis can be excluded it is necessary to make not only a careful clinical study of the case, but also repeated laboratory investigations as well as *x*-ray examinations, since, unless these are conducted systematically, tuberculosis may escape detection or may be wrongly diagnosed.

577. J. LUKÁCS and Z. DIRNER (*Arch. f. Kinderheilk.*, March 28th, 1930, p. 116) remark that the question of the relation between measles and tuberculosis has recently been the subject of numerous discussions. Noeggerath and Eckstein, followed by Bisken, disputed the old view that measles increased the susceptibility to tuberculosis, or roused a dormant tuberculous process into activity. Klein's statistics indicate that it is only in young children that measles has a pernicious effect, although in older children as well the possibility of a slight recrudescence of tuberculous disease must be reckoned with in every case. Two explanations may be offered for this bad effect of measles: either a change has taken place within the organism which renders the conditions more favourable for the growth of tubercle bacilli, or the specific protective powers of the organism have decreased owing to the measles. All the existing knowledge supports the second explanation, and particularly the fact that the tuberculous reactions become negative in the course of measles, or at least much weaker than usual. Since the authors held the view that the changes in the system took place chiefly in the tissue fluids and blood, they determined to investigate whether the addition of the blood serum of patients in different stages of measles to cultures of tubercle bacilli favoured the growth of the organisms. Comparative ob-ervations showed that the growth of tubercle bacilli was exactly the same as that the presence of measles serum was exactly the same as that of cultures not containing this serum. It also made no difference whether the patient gave a positive or negative tuberculin reaction. The authors come to the conclusion that measles does not favour the development of tubercle bacilli, but assists the tuberculous process by reducing the systemic defences.

Surgery.

578. **Primary Carcinoma of the Lung.**

J. A. MILLER and O. R. JONES (*Amer. Review of Tuberc.*, January, 1930, p. 1) discuss the clinical aspects of primary carcinoma of the lung from a study of the literature and from their personal observation of thirty-two cases of which details are given. The condition, more correctly designated primary bronchial carcinoma, comprises three groups of cases—namely, carcinoma of the lining epithelium of the bronchi; carcinoma of the mucous glands of the bronchi; and that arising from the pulmonary alveoli. The physical signs are varied and are not pathognomonic. In early cases they may be absent, or be simply those of a localized bronchitis with signs of consolidation, and, as the disease advances, with dulness and tenderness over the area in which the patient complains of pain. An *x*-ray examination is the most valuable single means of diagnosing the presence of a tumour, and bronchoscopy should be performed in all cases of chronic pulmonary disease in patients over the age of 40, where the sputum findings are negative for tuberculosis and the diagnosis is obscure. Ten clinical types, distinguished by their pathology, symptomatology, physical signs, and *x*-ray and broncho-copic findings, are described, but the diagnosis of the disease is frequently not made during life, and in its early stages is rarely possible. The main lines of treatment are at present symptomatic, though two cases have been recorded in which early tumours in the wall of the bronchus have been successfully removed with no recurrence four and eleven years later. *X*-ray treatment has so far shown no ability to arrest the progress of the disease, though it may afford relief to pain; in one case it appeared to produce a more chronic condition, so that the patient lived for a further two years. Where there is obstruction of the bronchus with atelectasis of the lung *x*-ray therapy may aggravate the symptoms, and in such cases it should not be used even to relieve pain. The thirty-two reported cases were observed during the past six years, and the diagnosis in each was substantiated by bronchoscopy or necropsy.

579. Appendicitis and Pyosalpinx with a Vesical Fistula.

BARBET and PASTEAU (*Bull. et Mém. Soc. des Chir. de Paris*, March 7th, 1930, p. 182) report a case of a girl, aged 21, who was under treatment for several years prior to operation for pyelonephritis by means of an auto-vaccine. When the symptoms became more severe a cystoscopy was performed and revealed a vesical fistula to the outside of the right ureteric orifice. In addition, there was tenderness on pressure over the appendix, and on rectal examination a mass was found on the right side of the pelvis. Consequently, a diagnosis was made of appendicitis, with an abscess opening into the bladder behind the right ureter. Laparotomy disclosed an appendix adherent to the mass in the pelvis and stenosed by an old attack; the appendix was removed. There was also evidence of an abscess localized by adhesions, with a large pyosalpinx adherent to the bladder, and communicating with it by means of a vesical fistula. The right ovary was partially destroyed and adherent to the Fallopian tube. The right adnexa were removed, and a catheter was left in the bladder. The patient made an uninterrupted recovery, was married six months after her operation, and has since given birth to two healthy children.

580. Nephroptosis.

G. GARRY and A. DRUCKMANN (*Zeit. f. Urol.*, Band 24, Heft 4, 1930, p. 241) have made a radiological study of normal persons, cases where the kidneys are palpable, and patients with indefinite abdominal and lumbar pain, pyelograms being taken in the sitting and lying positions. Theoretically the length, and the presence or absence of kinking or looping of the ureter, should distinguish between nephroptosis of congenital or acquired origin; in 80 per cent. of low kidneys they found a short straight ureter, but this criterion cannot be taken as absolute, since long kinked ureters can also be found with high or normally placed kidneys. In 52 per cent. of cases the position of the kidney was unaltered whether the patient was sitting or lying; in the rest it was 2 to 4 cm. lower in the sitting position. This movement however, was as commonly found in the high as in the low kidneys, so it is not necessarily a sign of ptosis. The movement of the kidney on sitting was accompanied by bowing of the ureter in 46 per cent., angulation in 17 per cent., and marked kinking in 37 per cent., the type of curve being constant in the same patient on re-examination months later. Even a low kidney accompanied by kinking of the ureter must be accepted with great caution as a cause for pain, however, as shown by some cases cited which were uninfluenced by nephropexy, but were cured when the real cause of the pain was later discovered and treated. On the other hand, dilatation of the renal pelvis in nephroptosis appears to cause definite symptoms, but is not necessarily associated with kinking of the ureter. In 7 out of 80 cases the ureter was found to arise not from the lowest part of the pelvis, but from a higher position, and this anomaly was associated with a dilated pelvis and renal symptoms in 5 of these, though only 2 had nephroptosis. The authors suggest that in some cases diagnosed as nephroptosis the pain is due not to the position of the kidney, but to an anomalous ureter arising from an abnormal situation in the pelvis and leading to interference with the outflow of urine.

581. Haemolytic Streptococcal Septicaemia.

C. S. ROLLER (*Amer. Journ. Dis. Child.*, January, 1930, p. 156), who records an illustrative case, has collected 43 cases of general sepsis observed at the Children's Hospital, Los Angeles, of which 10 were proved by blood culture during life to have been caused by the streptococcus. Five more cases were found to be streptococcal in origin by blood culture after death. Of the 43 patients, 40 died—a mortality of 93.1 per cent. All methods of treatment met with consistently poor responses. Roller's case was that of a male infant, aged 16 months, who developed acute haemolytic streptococcal septicaemia after mastoidectomy. Complete recovery ensued as the result of whole blood transfusions, anti-streptococcal serum, and intensive supporting measures such as the subcutaneous injection of saline solution, enemata of dextrose, and the administration of caffeine sodium benzoate, alternating with digitalis.

582. Chronic Infection of Cowper's Glands.

C. M. WHITNEY (*Urol. and Cut. Rev.*, April, 1930, p. 233), who records four illustrative cases in men aged from 28 to 34, states that infection of Cowper's glands may occur in three forms: the acute type, either with or without abscess formation; the subacute; and the chronic. The last form probably follows an acute infection, and if this is of a mild type no symptoms may be observed, except a recurrent urethral discharge. A chronic infection of Cowper's glands can often be diagnosed only by the occurrence of acute symptoms. The following diagnostic methods may also be of assistance. (1) Examination by combined rectal and perineal palpation. (2) Examination of the urine. The anterior urethra should be irrigated with boric acid solution and the washings saved. The urine should then be passed into two glasses and examined for shreds. If the wash-glass contains most of the shreds, they come from the anterior urethra, and probably from Cowper's glands. (3) Urethroscopy. The urethral mucous membrane is often much reddened at the site of the opening of the ducts of Cowper's glands. (4) Determination of the size of the urethra by a bougie, since occasionally an inflamed and enlarged gland may press on the urethra and narrow its calibre. The presence of stenosis is of value if a stricture can be excluded. Treatment consists in excising the diseased gland through a perineal incision.

Therapeutics.

533. Treatment of Vincent's Angina.

G. O. CUMMINGS (*New England Journ. of Med.*, April 17th, 1930, p. 768), who believes that the incidence of Vincent's angina has much increased during the last ten years, describes the condition as an ulcerated area on the tonsil or mucous membrane; the edges are red and irregular, while the base is firm and filled with adhesive grey necrotic tissue. It has to be distinguished from diphtheria, syphilis, and malignancy. The infective organisms, a fusiform bacillus and a spirillum, have been found in 50 per cent. of swabs from tonsils before, and 40 per cent. of swabs from tonsillar fossae three weeks after, operation in cases where there was no reason to suspect Vincent's infection. There may be severe pain or only discomfort on swallowing; the lymph nodes at the angle of the jaw are usually swollen and may be intensely tender. Constitutional symptoms are usually present for a few days and may be severe. The tonsil may slough away almost entirely in neglected cases. During the stage of invasion the patient should be kept in bed, with laxatives, antiseptics, and bland diet. Hot or cold packs on the swollen glands and gargles containing astringents, such as glycerin of tannic acid, and non-irritating antiseptics, such as hydrogen peroxide, afford comfort. The gingival sulcus about the teeth should be flushed out with a 1 in 500 solution of hexyl-resorcinol, using a syringe having a blunt-pointed needle set at an angle with the long axis of the syringe. Applications of 5 per cent. chromic acid are recommended, but no value is attached to silver nitrate or tincture of iodine. Pledgets of cotton-wool may be damped, rolled in powdered sodium perborate, and left in position around the gums for five minutes, or the perborate may be used as a dentifrice; it liberates free oxygen. Intravenous injections of salvarsan are not advised until less drastic treatment has failed; in severe cases, resisting the ordinary local and general medicaments, intravenous injections of 5 c.cm. of a 1 per cent. solution of antimony potassium tartrate may be tried. In convalescence the danger of recurrence owing to the use of an infected tooth-brush has to be borne in mind.

584. Liver Treatment in the Pernicious Anaemia of Pregnancy.

R. PETERSON, H. FIELD, jun., and H. S. MORGAN (*Journ. Amer. Med. Assoc.*, March 22nd, 1930, p. 838) report three cases of the pernicious or haemolytic anaemia of pregnancy which were treated with a high liver diet or liver extract. Though the results were complicated by transfusions in two cases, the response to liver treatment seems to have been quite analogous to that obtained by this therapy in primary pernicious anaemia. One patient was relieved by the treatment, but did not become well until after the termination of pregnancy; it is concluded that in this case the treatment had made possible a more normal type of blood regeneration but had not affected the underlying cause. In the majority of these pregnancy anaemia cases the condition is severe and often fatal. The colour index is high; there is a high-grade poikilocytosis and anisocytosis with megalocytes and frequently megaloblasts, and the blood bilirubin is increased. In distinction to the primary type, the macrocytosis is less marked, the leucocytes are more frequently normal or increased in number, and, if recovery occurs, there is little tendency to a relapse. A further difference is that achlorhydria is not a necessary concomitant. Free hydrochloric acid was found in the gastric contents of each of the three patients. Attention is drawn to the possible danger of high liver feeding during pregnancy when there is a tendency towards nephritis or toxaemia. The authors recommend especially careful observation of the urine and blood pressure when a high liver diet is given during pregnancy. One case afforded some evidence that liver extract might be as efficacious as liver; if so, it would avoid the danger emphasized, and be the most desirable treatment during pregnancy.

Administration of Strophanthin.

585. STROPHANTHIN has been associated with the digitalis derivatives and its action has been erroneously compared with that of digitalis; E. E. CORNWALL (*Med. Journ. and Record*, April 2nd, 1930, p. 355) enumerates some of the differences. In contrast with the effect produced by digitalis, the heart, after strophanthin poisoning, is found to be rigidly contracted; strophanthin does not affect the vagus mechanism, and appears to act by direct contact in increasing myocardial contractility and tonicity; finally, it has no cumulative action. If good results are to follow its administration, strophanthin must be given in proper doses. It has generally been considered that this drug should be employed only as an emergency method and in large doses; Cornwall, however, maintains that in smaller doses it can be continued for long periods, being often effective in prolonging life in cases of myocardial degeneration with heart failure, especially if its use is combined with a wise regulation of the physical activity and diet. The method of administration is of prime importance. Strophanthin is apparently used up in the body; it is not eliminated by the urine, saliva, or faeces. It may be given by intravenous, intramuscular, or hypodermic injections, or sublingually. In the majority of cases the last-named method suffices, and hypodermic injections in the bulk of the remainder, intramuscular and intravenous injections being only emergency methods. It should not be administered orally, since the amount which reaches the heart muscle by this route is too uncertain. The indications for the use of strophanthin and the dosage to be properly employed are dealt with. The great indication for its use is myocardial insufficiency. Heart failure from an impending arrhythmia, such as auricular fibrillation, calls for strophanthin only when there is also some intrinsic myocardial weakness, but it is indicated in all forms of myocardial disease with regular rhythm and signs of heart failure. In the cardiac failure of pneumonia and chronic myocardial degeneration, including hypertensive heart failure, this drug is most effective. It is also indicated in acute endocarditis with heart failure; in the cardiac failure occurring in acute febrile diseases; in chronic valvular disease, particularly in aortic and mitral incompetency; and in mitral stenosis with auricular fibrillation and heart failure, if there is much intrinsic myocardial weakness. As a general rule, ambulant patients should not receive more than 0.001 grain sublingually every four hours; if larger doses are necessary the patient should be put to bed.

Ophthalmology.

Subhyaloid Haemorrhage.

586. F. O. SCHWARTZ (*Amer. Journ. of Ophthalmol.*, March, 1930, p. 195) asserts that the presence of extravasated blood between the retina and vitreous is uncommon; it is very infrequent in adults and rare in children, except as a result of traumatism. These haemorrhages are usually of large size, covering the entire macular region, and including an area several disc diameters in the vertical and horizontal directions. The haemorrhage rarely reaches the temporal border of the disc, although cases have been known in which a portion of the nerve head was covered. More than one mass of blood may be present in the eye at one time; as many as three haemorrhages have been found in one eye, one small haemorrhage being on the optic disc, and accompanying two large subhyaloid ones. The condition appears suddenly in an apparently normal eye without any premonitory symptoms; tuberculosis, syphilis, focal infections, hyperthyroidism, and disease of the suprarenals are among the causes responsible for such effusions. Vision is greatly reduced, and objects appear reddish-brown or grey-green. The blood spreads equally in all directions and forms a thin layer, frequently assuming a number of shapes. The pre-retinal mass of blood may be separated into parts: a pale upper part and a dark lower. This division is caused by the settling of the corpuscles to the bottom of the still fluid blood. The line of contrast formed is straight and may be maintained upon inclination of the head; in rare cases this edge shows a concavity, but it may be convex. It is not difficult to recognize the condition. A favourable prognosis can be given, since full recovery of sight often occurs. Treatment is simple, comprising complete rest, supplemented by the administration of diuretics, cholagogues, and diaphoretics. Mercury and iodine are useful. Schwartz describes the case of a man, aged 23, who, while diving, struck the left temporal region of his head on the edge of a rock. Fifteen minutes later he noticed a greyish-green scotoma in the line of sight of the right eye; vision of this eye became generally obscured, and was limited to light perception. The man made an uneventful recovery; four weeks after the occurrence the vision had improved to 20/19, there being then no trace of the haemorrhages within the eye, while two and a half years after the accident his vision was 20/12, and he had a normal fundus.

Plasmoma of the Conjunctiva.

587. P. S. SOUDAKOFF (*China Med. Journ.*, March, 1930, p. 195) records seventeen cases of conjunctival plasmoma which he has encountered during the last seven years. The disease begins as a small growth of the fornix, spreading thence over the conjunctiva. Histologically it is a diffuse subepithelial plasma-cellular infiltration with which is associated a slight degree of hyaline degeneration of the connective tissue stroma. The condition is not a tumour, but a tissue reaction due to chronic irritation. Most patients with plasmoma also suffer from trachoma, and the author believes that the toxins of the latter play an important part in setting up the irritation which eventually gives rise to plasmoma. Treatment consists in early and complete excision of the growth, followed by radium.

Ocular Lesions in Oxycephaly.

588. A. COLRAT (*Journ. de Méd. de Lyon*, March 20th, 1930, p. 179) states that in oxycephaly the cranial deformity is accompanied by marked radiological signs and frequently by ocular troubles. The deformity is due to an abnormal height of the cranial vault, but its configuration varies in different cases. Usually the forehead is almost vertical, descending nearly perpendicularly on the naso-frontal juncture; sometimes it is slightly inclined behind; and sometimes it is prominent and the vertical plane passes in front of the orbital arcades. In typical cases the curve of the vertex is rounded from before backwards, making a marked prominence at the centre of the naso-inial line. The occipital region, as a rule, is flat. A slight prognathism of the superior maxilla exists, and the face and cranium in a general way are elongated and retracted transversely. Radiographs show particularly a falling-in of the middle portion of the base. The eyes are often prominent, and a diminution of vision may occur at various periods. The ocular lesion commences as a papillary oedema, but it is rarely noted at this stage when treatment would be of avail. This diminution of vision is caused by a post-neuritic atrophy, very often more marked in one eye, which ends in a more or less total blindness. The exophthalmos is often marked, and strabismus is very frequent. Other symptoms are not constant. Some children show meningeal crises (headaches and convulsions), but these are rare. Usually the intelligence is normal and the development satisfactory, except in cases of early blindness. These lesions appear to be due to a chronic meningitis of vague etiology, which causes a premature synostosis of the frontal and sagittal sutures, and secondarily an intracranial hypertension. This in its turn brings about the basal falling-in and papillary oedema, and later atrophy of the optic nerve. Early diagnosis is necessary to initiate successful treatment, thus preventing blindness; decompressive trephining is the method of choice. Two allied conditions are described: the cranio-facial synostosis of Crouzon, and the acrocephalosyndactylia of Apert. The former is characterized by a slightly analogous deformity of the cranium with a pseudo-acromegalic aspect of the face, but without marked basal falling-in. The latter shows a cranial malformation similar to that of Crouzon's disease, but with total syndactylia of all the extremities.

Obstetrics and Gynaecology.

The Time of Ovulation in the Menstrual Cycle.

589. Q. U. NEWELL, E. ALLEN, J. P. PRATT, and L. J. BLAND (*Amer. Journ. Obstet. and Gynecol.*, February, 1930, p. 180) have made an investigation into the time of ovulation in women, the menstrual history being correlated with careful macroscopical and microscopical observations of the corpus luteum. An attempt was also made to recover the corresponding ovum from the Fallopian tube. The material was selected from routine operations. A technique was devised whereby the tubes were irrigated with normal saline; the washings were collected in watchglasses, and were later searched for ova. The authors believe this method to be quite safe. Information about the presence of ova can be obtained from tubes which show no pathological lesion and are therefore left *in situ*. The method was also found useful in determining the patency of the tubes. More than ninety operations were performed at various stages of the menstrual cycle. Nine specimens were removed from the Fallopian tubes, five of which were definitely identified as tubal ova by examination of sections. From the data thus obtained the

time of ovulation occurred on, or one or two days before, the fourteenth (morning of the fifteenth) day following the onset of the previous menses. It appeared that the ovum had completely degenerated after the twenty-first day of the menstrual cycle, and, whether remaining in the tube or uterine cavity, would probably be incapable of undergoing fertilization.

590. Endometriosis.

J. V. MEIGS (*New England Journ. Med.*, April 3rd, 1930, p. 672) records four cases of endometriosis, each of which throws some light upon the debatable questions as to the age of incidence, conservation in treatment, atrophy after castration, and the etiology and prevention of growth in the operative scar. While it is generally thought that endometriosis usually occurs after the twenty-sixth year, the first case occurred in a girl aged 23, in whom the condition must have been present before the twentieth year. The second case shows that conservative surgery may be a safe procedure, though it is generally held that removal of all ovarian tissue in order to ensure cessation of growth is the wisest treatment. In this case, from which a large cyst of the right ovary and a smaller one from the left ovary were removed, the remainder of the left ovary and the uterus being conserved, the menopause did not ensue till ten years later; menstruation was regular till then, and there were no signs of recurrence at the end of that time. The third case is quoted as proving that endometriomas may atrophy and completely vanish following bilateral oöphorectomy, without leaving any palpable or visible sign. The questions why some endometriomas occur in abdominal scars, and how such recurrence can be prevented, are answered by the fourth case, in which the tumour probably grew from the fundus of the uterus, which had been sutured into the abdominal wound. Whenever, therefore, round ligament suspension, fixation, or intra-abdominal wall fixation of the uterus is contemplated in such a case penetration of the endometrial cavities by the stitches must be avoided if the risk of growth in the operative scar is to be prevented.

591. Radium Treatment of Carcinoma of the Cervix.

P. PETIT-DUTAILLIS (*La Gynécol.*, February, 1930, p. 99), as a preliminary to radium treatment of cancer of the cervix, recommends removal by a sharp curette of as much as possible of the growth, followed by thorough cauterization of the bleeding surface. He has not found that these measures are followed by serious haemorrhage, infection, or perforation of organs; they have the further advantage that the subsequent insertion of radium in the corporeal canal (reconstructed by the cautery, if it has been destroyed by the neoplasm) or in the deepest parts of the growth is easy. From these situations radiation of the internal iliac lymphatics and gland is secured, and slight filtration only (1 mm. of platinum and a few layers of gauze) is necessary; the radium, which is placed at the same time in the vaginal fornices, requires, however, very thorough filtration. The dose used is 10 millicuries destroyed daily for seven to eight days. For the purpose of peripheral radiation in cases in which the parametrium is widely invaded, the radium is inserted through the perineum and passes between the obturator internus and its aponeurosis in front of the great sciatic notch, whence not only the internal but also the external iliac glands are exposed to radio-activity. The parametrium is subjected to cross-fire from this situation and from radium placed in the utero-vaginal zone. Three cases of extensive parametrial carcinoma failed to respond to this treatment; but in a fourth advanced case, that of a patient aged 51 in whom radium treatment had been regarded as useless and probably harmful, curetting with cauterization and the application of 66 millicuries of radium destroyed in four days were followed by cure, which has been maintained for more than six years. Two months after treatment the patient had obturator neuralgia, and a fistula along the track of insertion of one of the radiferous tubes in the pelvic wall.

Pathology.

592. Blood Groups in Shansi.

J. A. CURRAN, E. C. ROSENOW, jun., and S. T. FENG (*Nat. Med. Journ. of China*, February, 1930, p. 75) have investigated the blood groups of the province of Shansi, an isolated country north-east of the Yellow River, where during recent centuries emigration and immigration have been slight. One thousand examinations were made from patients, members of the staff, and students in the Fenchow hospital, all the persons tested being of Shansi origin. In the method employed 2 to 3 drops of blood were dropped into 5 c.cm. of normal saline solution; a drop of anti-A serum and one of anti-B serum were pipetted on to separate marked cover-slips and a drop of the cell suspension was added to each; the preparations were well mixed, mounted on hollow-ground slides, incubated for fifteen to twenty minutes at 37° C., and then examined under a low power. The letters O, A, B, and AB were adopted for designating the four groups in accordance with the recommendation of the League of Nations. The biochemical racial index calculated from the ratio $\frac{A + AB}{B + AB}$ was 0.739, bringing the people of Shansi within the Indo-Manchurian group, though this index is slightly lower than the previous figures reported for China. The table of findings for other provinces investigated by various observers is useful for comparison. The authors add that the examinations made at the Fenchow hospital were of great assistance in obtaining data as regards possible donors for transfusion.

593. Specific Antibody Absorption by the Viruses of Vaccinia and Herpes.

W. SMITH (*Journ. Path. and Bact.*, April, 1930, p. 273) has performed experiments on the absorption of protective antibodies from anti-vaccinial and anti-herpes serum. The general technique was to mix the serum with large quantities of infected tissue suspension, incubate for three days in the presence of ether, centrifuge the mixture, filter the supernatant fluid through L2 candles, and test the filtrate for protective power against the homologous virus. The results showed that vaccinial and herpes testicular suspensions were capable of absorbing to some extent their homologous antibodies from immune serums. The specificity of the absorption was shown by cross-absorption tests, in which vaccinial testis failed to remove the antibodies from a herpes immune serum, and herpetic testis failed to remove the antibodies from a vaccinial immune serum; also by the fact that each virus removed only its own antibodies from a mixture of the two serums. When a vaccinial testis suspension, in which the virus had been killed by heating at 58° to 60° C. for one hour, was used for absorption, the antibodies were removed to only a slight extent. The author considers that these experiments suggest the probability of a direct union between antigen and antibody *in vitro*.

594. The Etiology of Cancer.

CITING Cramer to the effect that freedom from cancer is more likely to be attained by diminishing the susceptibility to this morbid change than by trying to hunt down various forms of chronic irritation, J. A. SHAW-MACKENZIE (*Journ. Trop. Med. and Hyg.*, May 1st, 1930, p. 117) recalls his suggestion made twenty-five years ago that cell proliferation or alteration of the type of division may be dependent on some systemic condition, and that local irritation determines the site of growth. After testing the effects of injecting different tissue extracts, certain biochemical conclusions were reached, the first of these being that variations in the action of serum on the ferment lipase occur in cancer and other diseases. When normal serum is added to pancreatic extracts or to the secretion itself, fat-splitting is markedly increased; serum does not split fats, but contains an activator. When carcinoma serum is added the fat-splitting is decreased; the serum then contains some inhibiting factor. In cases of recovery the action of the serum returns to normal or is increased. It was deduced from these experiments that the increased lipolytic activity is a factor which prevents the development of cancer, and favours its disappearance when present; it is associated with the resistance of the body to cancer. Discussing proteolytic and peptolytic factors, the author suggests that, in the case of lipase, a failure of response in an organ other than that of the one affected by cancer may be a possible factor in the development of this condition, and also that as a result of deficient digestive ferments the cells of any focus of lesser resistance would become overcharged with peptone, glycogen, fats, carbohydrates, etc., thus approximating to the foetal type of cell with its reproductive cell activity. Other points discussed are inhibiting factors, local aspects, the developmental factor, fatty acid in immunization, and some reactions of cancer in relation to diagnosis and treatment. Since in cancer there is not only deficient enzyme action in the case of lipase but of other enzymes, Shaw-Mackenzie suggests that in the remarkable results obtained by Murphy and Leitch in producing tumour by chemical substances from normal tissues, the substance isolated might be of the nature of an inhibitor or paralyser of normal enzyme action, a direct ferment action not being concerned. In conclusion, he states that systemic defensive factors have been demonstrated in natural and induced tissue lipolysis, in striking contrast to defective lipolysis in cancer and other diseases, and that this knowledge applied to treatment in inoperable cases of human carcinoma had met with some success. Whether defective tissue lipolysis and utilization of fats or defective oxidation, or both these factors, be the cause of the known excess of unsaturated fatty material in cancer, it is a fact that considerable alteration in the metabolism of fats and lipoids occurs in the blood and tissues in this disease.

THE MODERN PRACTICE IN CALCIUM THERAPY

THE SIGNIFICANCE OF REGULATION

MODERN research has shown that calcium and vitamin D in the body cannot be thought of in separate terms—the two form a bio-chemical entity. In the absence of vitamin D calcium is not utilised by the body. Vitamin D has therefore assumed a foremost position in therapeutics. The latest pronouncement on the subject from the Lancet of May 10th is significant:—

"The stores of calcium in the body are large and it is usually the regulating mechanism that is at fault, not the supply. From this it follows that the use of cod-liver oil, ultra-violet light, irradiated ergosterol, parathyroid and thyroid extract may have greater value than the administration of calcium." (*Lancet, May 10th, 1930*).

For over five years the Glaxo Laboratories have been investigating vitamin D, its preparation, its nature and its mode of action.

Ostelin is the name we gave five years ago to the first physiologically standardised preparation of vitamin D. It is made to-day by irradiation of ergosterol and is available in various forms and preparations which cover the whole field of the modern practice in the therapeutic uses of calcium.

THE "OSTELIN" PREPARATIONS

As now prepared by irradiation, "Ostelin" vitamin D is tasteless. The potency is assured by physiological test at the uniform standard which has been maintained for over five years.

"OSTELIN" LIQUID

3 minims equivalent in vitamin D value to 1 drachm of cod-liver oil.

"OSTELIN" TABLETS

"Ostelin" vitamin D: calcium glycerophosphate.

COLLOIDAL CALCIUM with "OSTELIN" vitamin D

Each 1 c.c. ampoule contains 0.5 mgm. calcium in the colloidal state.

"OSTOMALT"

"Ostelin" vitamin D: malt extract: orange juice: and calcium glycerophosphate.

ELIXIR "OSTELIN"

For incorporating in aqueous and spirituous mixtures.

"OSTELIN" WITH PARATHYROID TABLETS

3m. "Ostelin" Liq. 2 grs. calc. glyc. 1/40th gr. parathyroid sicc.

"OSTELIN" EMULSION

Ostelin Emulsion contains "Ostelin" vitamin D and calcium glycerophosphate and is prepared under such control conditions as ensure its absolute stability.

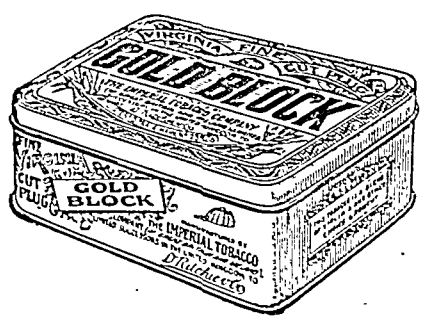
This very palatable preparation is of wide use—for adults and children. In the general treatment of ailing children its administration over considerable periods produces very good results in all cases.

Ostelin Emulsion is a strictly economical preparation. For prolonged administration 2 or three times a day will be found an effective dose.

Supplied in bottles containing 8 fluid oz. @ 2/6d per bottle from chemists, or, at the usual professional discount, direct from:—

GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1.

ASSISTANCE FOR THOSE TREATING SKIN COMPLAINTS



The lessons of the great war added nothing more clearly to the knowledge of the treatment of skin troubles than a realisation of the healing virtues of peat. Used for wounds and for skin diseases, this natural remedy met with the most gratifying success. You can use it conveniently and cheaply if you select from the list of Sphagnol preparations whichever is most suitable for your purpose. There is an ointment, soaps (medical, toilet, and shaving), suppositories, and a lotion. All contain 5, 10, or 15 per cent. of the principle in a medium of the highest quality. All are obtainable from your own chemist.

In order that you can test their efficacy the makers are always glad to send free samples to medical practitioners who write to Peat Products (Sphagnol) Ltd. (Dept. B28), 21, Bush Lane, London, E.C.4.

CITY OF LONDON MENTAL HOSPITAL, DARTFORD, KENT.

PRIVATE PATIENTS are received at a weekly charge of TWO GUINEAS and upwards, and VOLUNTARY BOARDERS can now be admitted.—Apply to the MED. SUPERINTENDENT.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion *bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc.* There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

BELVOIR NURSING HOME,

SWISS SPAS.

BADEN.

On the main line Zürich-Basle and Zürich-Berne. The hot springs of Baden were already known to the Romans. 17 radio-active wells at a temperature of 118.4°F. They contain sulphur and sodium-chloride. The baths are obtainable in the hotels themselves. Treatments: warm baths, shower baths, massage, electric baths, inhalation, drinking cure, diagnostic-therapeutic institute, mechanotherapy. Recommended for metabolic diseases, rheumatism, gout, sciatica, diseases of the muscles, bones, and joints, retarded convalescence after injuries and operations.
Season: April 1st to November 1st.
For information apply to: Spa Director, Baden, Switzerland.

LOÈCHE-LES-BAINS.

One hour by electric railway from Loèche (main station on the Simplon route). Mild alpine climate. The baths were already known to the Gauls and Romans. The radio-active springs contain chiefly sulphate of lime. Two swimming pools. Every hotel has its own bathing installation. Treatments: warm baths, douche-massage, injections, air and sun baths. Recommended for: gout, rheumatism, sciatica, anaemia, post-operational conditions, convalescence, gynaecological diseases, circulatory disturbances, skin diseases.
Season: May to October.
For information apply to: Hotel Association, Loèche-les-Bains, Switzerland.

PASSUGG.

Near Chur. Situated on a picturesque plateau. Mild sub-alpine climate. Vast forests.
Treatments: The Ulricus spring (alcaline-muriatic), Belvedra spring (chalybeate), Fortunatus spring (alcaline-muriatic with iodine), Helen spring (mildly alcaline and acid), Theophil spring. All varieties of accessory treatment. Dietetic treatment. Indications: Diseases of the digestive organs, diseases of the liver and bile ducts, kidney and bladder diseases, diseases of nutrition and metabolic diseases, especially diabetes, arterio-sclerosis, diseases of the blood and tropical diseases.
Season: May to October.
For information apply to: Spa Director, Passugg, Switzerland.

RHEINFELDEN.

10 miles from Basle, on the railway line Zürich-Basle. Famous for its vigorous brine, containing 31% salt, and for its "Kapuziner" spring, a highly diuretic calcium and boric acid well, and for "Magdalena" spring, containing sulphates of calcium, sodium, and magnesium. 8 bath establishments with up-to-date installations. Treatments: brine baths, carbonic acid brine baths, drinking, mud packs, "Mutterlauge" packs, inhalation, massage, gymnastics, all varieties of electric treatment, dietetic treatment. Recommended for: gout, rheumatism, arthritis, women's diseases, sterility, obesity, children's diseases, arterial hypertension, diseases of the heart, affections of muscles, bones, and joints, convalescence.
Any information and detailed booklet gladly supplied by: Enquiry Office, Rheinfelden, Switzerland.

SCHINZNACH.

Railway connections: Basle-Brugg-Zürich, and Berne-Brugg-Zürich. The hot springs of Schinznach were in use in Roman times and belong to the strongest radio-active sulphur wells on the Continent. Newly equipped, comfortable baths and inhalation rooms. Treatments: baths, drinking, sulphur-mud and sulphur-water packs, irrigations, inhalatorium, massage, X-rays. Recommended for: gout, rheumatism, affections of bones and joints, non-tuberculous catarrhs of the air passages, arterio-sclerosis, diseases of the skin, diseases of women, children's diseases.
Season: May to October.
For information apply to: Spa Director, Schinznach Bad, Switzerland.

TARASP-SCHULS-VULPERA.

The chief spa of the Lower Engadine. Glauber salts wells. The advantage of this spa lies in the combination of the curative properties of the waters with the alpine air and sun.
10 mineral springs of various composition. Up-to-date equipment for drinking and baths, air and sun baths, swimming baths, Zander-hall, X-ray institute, diet. Recommended for: affections of the digestive organs, metabolic ailments, nervous troubles, affections of the organs of circulation, of the organs of respiration, of the genito-urinary system, malaria.
Information supplied by: General Manager, Kurhaus Tarasp.

For information and the booklet "Swiss Spas and their Mineral Springs" (sent gratis), please apply to the Office of the Swiss Federal Railways, 11b, Regent Street, London, S.W.1.

ABERNANT LAKE HOTEL,
LLANWRTYD WELLS, CENTRAL WALES.

A First-class fully licensed Hotel, not a Sanatorium, 750 ft. above sea-level, amidst beautiful scenery, standing in grounds of 400 acres. Electric light, central heating, billiards, own golf links, 4 miles preserved trout fishing, exclusively reserved for Hotel Guests, tennis, 18 hole putting course, boating, bathing, shooting, riding. Sulphur Spring in grounds. An ideal home for those wanting a sporting and peaceful holiday away from the crowd.

Special reduced terms for the Medical Profession.

THE HARROGATE FOAM BATH

THIS is a new development in treatment in which Harrogate Natural Sulphur Water is used in the form of Foam with air, oxygen, or carbon dioxide. This bathing medium has a density of only one per cent. of that of water. The negligible hydrostatic pressure makes it suitable in heart cases, in arterio-sclerosis and other disorders of the vascular system. Exhaustion is completely absent. The only sensations are of comfort and refreshment.

The thermal non-conductivity of the foam leads to profuse sweating and increased metabolism.

Indications: Obesity, Gout, Arthritis, and other rheumatic affections, such as Fibrositis and Lumbago.

Pullman and Fast Restaurant Car Trains daily from King's Cross Station, London.

Medical and "lay" brochures, with details of Complimentary Facilities offered to the Medical Profession, free upon application to F. J. C. Broome, General Manager, 3, The Royal Baths, Harrogate.

Salary of Senior House Surgeon at the rate of £200 per annum and Junior House Surgeon £150 per annum, with board, residence, and laundry. Three residents are employed.

Appointments for not less than six months. Candidates eligible for higher posts as they become vacant.

Applications, stating age, nationality, and previous experience, with three recent testimonials, should be sent to the undersigned as soon as possible.

CHARLES POSTGATE, Secretary-Superintendent.

UNIVERSITY OF LONDON.

EXTERNAL EXAMINERSHIPS, 1931.

The Senate announce the following vacant External Examinerships for all Examinations above Matriculation for the year 1931. Except when otherwise stated, Examiners will act in all Examinations in which the subject is included.

For the First Examination for Medical Degrees.

CHEMISTRY.

For the Second Examination for Medical Degrees

PHARMACOLOGY.

For Final and Higher Examinations for Medical Degrees.

MEDICINE. SURGERY.
OBSTETRIC MEDICINE.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it.

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable, on or before Monday, July 7th, 1930. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

University of London, South Kensington, S.W.7. June, 1930. EDWIN DELLER, Principal.

Prifysgol Cymru.

Instruction is given daily except on Saturdays.

The Course will continue until the end of July. There will be a vacation during the whole of August, classes resuming first week September.

FEES.—£12 12s. each subject or £21 for both.

City of Plymouth.

MEDICAL SUPERINTENDENT.

(AMENDED ADVERTISEMENT.)

Applications are invited from duly qualified and registered Medical Practitioners for the post of Medical Superintendent of the PLYMOUTH CITY HOSPITAL.

The salary will be at the rate of £1,000 per year, with an allowance of the sum of £250 in lieu of quarters, etc. No canvassing for this appointment is permitted, and any canvassing will disqualify the applicant. The appointment will be terminable by three months' notice on either side.

Personal experience in Hospital administration is essential. The appointment is whole-time and private practice is not permitted. The person appointed will be an Assistant Medical Officer in the Public Health Department, and will be on the staff of the Medical Officer of Health, who is the General Medical Superintendent of the Corporation Hospitals.

Applications will be considered only on the forms of application which will be provided. A form of application, together with further details relating to the appointment, can be obtained from the undersigned, on the receipt by him of a request for this, accompanied by a stamped and addressed foolscap envelope. Forms of application, duly completed, *together with* copies of not more than three recent testimonials, must be returned to the undersigned not later than Saturday, July 12th.

Town Hall, Stonehouse, Plymouth. June 21st, 1930. A. T. NANKIVELL, M.D., M.R.C.P., D.P.H., etc., Medical Officer of Health.

City and County of Newcastle-UPON-TYNE.

CITY HOSPITAL FOR INFECTIOUS DISEASES.

RESIDENT MEDICAL ASSISTANT (Male).

Wanted immediately, a Resident Medical Assistant (male), who holds a registrable qualification in Medicine and Surgery (and preferably also in Public Health), and possesses a practical knowledge of Bacteriology. The holding of a previous resident appointment and some experience of general practice will be considered a recommendation.

Salary £350 per annum, with board, lodging, etc.

Applications, stating age, qualifications, and previous experience, to be forwarded with copies of not more than three recent testimonials, to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

June 23rd, 1930.

Royal Salop Infirmary, SHREWSBURY. (150 Beds.)

APPOINTMENT OF RESIDENT SURGICAL OFFICER.

Applications are invited from fully qualified men for the appointment of RESIDENT SURGICAL OFFICER, vacant immediately. The appointment is for a period of 12 months, at a salary of £200 per annum, with board, residence, etc.

The Resident Surgical Officer is Senior Resident Officer of the Hospital. House Staff comprises House Physician and House Surgeon.

Applications, stating age, qualifications, experience, nationality, and accompanied by copies of three testimonials, to be sent to the undersigned.

June 21st, 1930. J. W. NOBLE, Secretary-Supt.

WEST AFRICAN MEDICAL STAFF.

Vacancies at present exist for MEDICAL OFFICERS in the WEST AFRICAN MEDICAL STAFF.

Qualifications. Candidates must be British subjects of European parentage and under 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

Salary. £660 per annum, rising by annual increments of £30 per annum to £720 per annum, and then, on confirmation, £720 per annum, rising by annual increments of £40 to £960 per annum, together with a seniority allowance (payable only in West Africa) at the rate of £72 per annum. After three years' service on £960, the salary may be raised to the scale of £1,000 per annum, rising by annual increments of £50 to £1,150 per annum, together with a seniority allowance at the rate of £100 per annum.

Quarters. Free quarters are provided or an allowance is given in lieu.

Outfit Allowance. An outfit allowance of £60 is granted on first appointment and when proceeding on or returning from leave. A married officer will, in certain circumstances, be granted

Passages. Free first-class passages are provided for the officer only both on first appointment and half the cost of his wife's passages to and from West Africa.

Terms of Appointment. The appointments are pensionable, subject to a probationary period of three years in the first instance.

Tour of Service. The normal tour of service in West Africa is approximately 18 months, though vacation leave may be granted by the Governor after 12 months, and is followed by leave at the rate of one week for each completed month of residential service, plus the time necessarily spent in the voyages to and from England.

Course of Instruction in Tropical Medicine. Selected candidates will normally be required to attend a course of instruction in Tropical Medicine and Hygiene before proceeding overseas.

Duties. Though Medical Officers are appointed in the first instance for general service, there are good opportunities for work in special branches of medicine and surgery and for research.

Further particulars and forms of application may be obtained, on application in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Egyptian Government.

EGYPTIAN UNIVERSITY.

FACULTY OF MEDICINE.

Applications are invited for the newly created CHAIR OF PROFESSOR OF HYGIENE. Applicants must have a University Medical Qualification and at least ten years' experience of Public Health work, preferably in a Tropical country. Candidates must have a recognized qualification in Public Health and preferably a qualification in Tropical Medicine and Hygiene. They must have held a post in a recognized institute.

The duties of the Professor include giving a course of instruction to Under-Graduates and Post-Graduate Course for the Diploma of Public Health and Tropical Medicine. He will also conduct Research work. The language of instruction is English.

The salary offered is £E.1,500 (approximately £1 538) a year, and the appointment will be on contract for three years, renewable. The contract may be terminated by either side by three months' notice in writing.

One month's salary will be paid in lieu of travelling expenses if the successful applicant is resident in Europe.

If an official of the Egyptian Government is selected for the post he will not receive the advertised salary unless it is sanctioned by the Egyptian University, Cairo, so as to be received by him not later than September 20th, 1930.

Financial Authorities will not receive the applications, with copies of published Research and copies of testimonials, should be addressed to the Dean of the Faculty of Medicine, Egyptian University, Cairo, so as to be received by him not later than September 20th, 1930.

Further details may be secured by application to the DEAN.

Egyptian Government.

EGYPTIAN UNIVERSITY.

FACULTY OF MEDICINE, DENTAL SCHOOL.

Applications are invited for the post of LECTURER IN DENTAL SURGERY and ASSISTANT DENTAL SURGEON in the DENTAL SCHOOL, CAIRO. The duties will be instructional and clinical.

Preference will be given to candidates possessing the L.D.S.R.C.S.England.

The appointment will be on contract for three years at a salary of £E.480 (approximately £492) a year, and private practice is allowed.

One month's salary will be paid in lieu of travelling expenses if the successful applicant is resident in Europe.

Applications, with details of experience and copies of recent testimonials, should be addressed to the Dean of the Faculty of Medicine, Kasr-el-Aini, Cairo, so as to reach him not later than September 20th, 1930.

University of Manitoba,

WINNIPEG, CANADA.

FACULTY OF MEDICINE.

The post of ASSISTANT PROFESSOR OF ANATOMY in the University of Manitoba will be vacant from October 1st, 1930. Salary 3,500 dollars (200 in lieu of passage). Applications, with two or three testimonials, should reach me before August 6th, 1930.

Medical College, Winnipeg, Canada. S. W. PROWSE, M.D., Dean, Faculty of Medicine.

Durham County and Sunderland

EYE INFIRMARY.

Wanted, a LOCUM for the above Institution for about 10 (ten) weeks from July 7th. Must have good experience of Ophthalmic work. Apply, with full particulars, to JOHN BUTTERFIELD, Secretary, Eye Infirmary, Stockton Road, Sunderland.

Harrogate Infirmary.

One HOUSE PHYSICIAN and CASUALTY OFFICER. Salary £150 p.a.

The Hospital contains 216 beds, including 46 Maternity beds and other Special Departments.

Candidates, who should have previously held hospital appointments, must send applications, accompanied by testimonials, to the undersigned, not later than Thursday, July 3rd.

RAPHAEL JACKSON (Major), Secretary.

Jewish Maternity Hospital,

Underwood Street, E.1.

Vacancies occur for CLINICAL ASSISTANTS. Candidates, who must be registered Practitioners, are admitted to the practice of the Hospital for a period of three months for the payment of £5 5s. Applications should be submitted to the Secretary.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
			150	1st
Lieut.		500	150	2nd
			150	3rd
			150	4th
Capt.	(i) During first 3 years' service as Captain	650	£15	5th
			£15	6th
			£25	7th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	8th
			£25	9th
			£25	10th
	(iii) With more than 6 years' service as Captain	850	£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1 The Selection Committee will meet at the India Office in July, and the selected candidates will be required to join a course of instruction commencing early in August, 1930. Applications should be submitted as soon as possible.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE permanent COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in July, 1930. Applications should reach the War Office not later than July 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of July. They mus be under 28 years of age on August 1st, 1930, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—From £500 to £2,000 a year according to rank and length of service.

Gratuities on Retirement.—After 7 years' service £1,000.
" 15 " " £2,800.
" 18 " " £3,500

Current rates of retired pay range from £368 10s. per annum, normally earned by a Major after 20 years' service, to £930 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

A certain number of temporary Commissions will also be offered at the same time under the same conditions as regards age and qualifications as those required of candidates for permanent Commissions.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.I.), Whitehall, London, S.W.1.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A PART-TIME JUNIOR CASUALTY OFFICER is required on July 9th, to assist in the Casualty Department from 10 a.m. to 3 p.m. (Saturdays 10 a.m. to 1 p.m.), under the direction of the Casualty Officer.

The work of this Officer includes a large number of Tonsillectomies and other minor operations.

Candidates must be registered Medical Practitioners, and have held a responsible Hospital appointment.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, June 30th, accompanied by copies of not more than three testimonials written specially for the purpose.

The appointment is made for six months, and is non-resident.

Salary at the rate of £150 per annum, with luncheon.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, July 2nd, at 4.45 precisely.

Forms of application and copies of the rules may be obtained from the Secretary, at the Hospital.

By Order of the Board of Management,
JAMES McKAY,
June, 1930. Secretary.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A MEDICAL REGISTRAR and PATHOLOGIST is required on October 1st.

Gentlemen are invited to send in their applications, addressed to the Secretary, with copies of not more than three testimonials written specially for the purpose, before 12 o'clock on Monday, July 14th.

The appointment is made for one year, but may be held, subject to re-election, for three years.

Salary £300 per annum, with luncheon and dinner when on duty, and an allowance of eighteen guineas for the purpose of providing a substitute during annual leave.

Candidates must be registered Medical Men, and must have held a responsible Hospital appointment, and be prepared to take up the duties on October 1st.

All candidates must be in attendance at the Hospital to appear before the Joint Committee, if necessary, on Wednesday, July 16th, at 4.45 p.m.

Forms of application and copies of the rules for, and details of the duties of, the appointment will be supplied on application to the Secretary.

By Order of the Board of Management,
JAMES McKAY,
June, 1930. Secretary.

Borough of Ilford.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation invites applications from legally qualified Medical persons of both sexes for the office of Assistant Medical Officer of Health, for duties in connection with Maternity and Child Welfare work, School Medical Inspection, and General Public Health work. Candidates for the appointment must have had special qualification, and experience in Midwifery since qualification, and subject to this, preference will be given to candidates who possess the Diploma of Public Health or similar qualification, and have had definite experience in Children's Diseases.

The commencing salary of the officer will be £600 per annum (no bonus), rising by one annual increment of £50 and two annual increments of £25 to £700 per annum, subject to satisfactory service.

The person appointed will be required to devote whole time to the duties of the office, to reside within easy distance of the Corporation's Maternity Home, and to enter into an agreement for the due performance and fulfilment of all the duties and conditions governing the appointment. The appointment will be subject to a satisfactory medical examination and to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), endorsed "Assistant Medical Officer of Health," must be received at my office, at the Town Hall, Ilford, not later than Tuesday, July 1st.

Canvassing Members of the Council, directly or indirectly, is prohibited and will disqualify.

By Order, ADAM PARTINGTON, Town Clerk.

Town Hall, Ilford.

June 17th, 1930.

Lancashire County Council.

BIDDULPH GRANGE ORTHOPAEDIC HOSPITAL.

The Lancashire County Council invite applications for the post of RADIOGRAPHER (Non-resident) at the above Hospital.

The salary to be paid is £200 per annum, together with part board. Indoor uniform will also be provided after one month's service.

Candidates should possess a certificate in Radiography from the Society of Radiographers or from an approved training school. The person appointed must be prepared to carry out such other duties in addition to Radiography as may be required.

The person appointed will be required to pass a medical examination and to contribute towards the Council's Superannuation Scheme.

The appointment will be terminable by one month's notice on either side.

Applications, stating age, full details of previous and present appointments and experience, certificates held, etc., and accompanied by copies of two recent testimonials, are to be sent to the Secretary, Biddulph Grange Orthopaedic Hospital, near Stoke-on-Trent, not later than July 14th. Envelopes should be endorsed "Radiographer."

Tele. Address: Triform, Wesdo—London.

Oxford Street, W.1.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

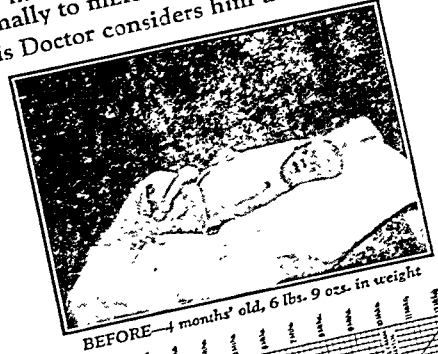
24. YORKS (NORTH RIDING).—In a small pleasant market town, with pretty and prosperous surrounding country, very old-established mixed-class PRACTICE averaging £1,247 p.a., including appts. worth £80 and panel producing last year £366. Visits 3/6 to 25/-. One opponent. Good house, facing south (3 reception, 5 bedrooms, bathroom, etc.). Garden. Garage. Electric light. Vendor's freehold. Price £1,350 (£1,000 on mortgage), or would let for few years at £80 p.a. Premium £1,500. Educational and social amenities.
25. SOUTH YORKS.—GOOD TOWN. — Old-established good middle-class PRACTICE, producing for last twelve months nearly £4,500. Small selected panel of 400. Fees 5/- to 10/-. Mid. 2 to 10 gns. (only about 50 cases yearly). Suitable house, with 3 reception, 6 bedrooms, etc., and professional rooms. Electric light. Good garden. Garage for 3 cars. Rent on lease £100 p.a. Excellent schools, sport, etc. Premium £5,700.
26. KENT.—Pleasant Seaside and residential Town (pop. 17,000).—Old estab. non-dispensing middle and working-class PRACTICE, averaging for the past 3 years over £1,050 p.a. including transferable appt. worth about £200 and panel of 500. Visits 3/6 to 10/6. House contains 8 rooms, kitchen, bathroom, etc. Garden. Garage. Price freehold £1,500, but might be rented. Premium £1,500.
27. MANCHESTER.—PRACTICE is situated in a growing district offering very large scope. Income about £1,700 p.a., including panel producing £430. Fees 3/6 upwards. Excellent detached house, well situated, with 3 reception, 5 bedrooms, etc., all in good order. Price £1,800. Premium 1½ years' purchase.
28. LONDON, SOUTH-WEST.—Very old-established non-residential PRACTICE, averaging about £4,000 p.a. Panel of 1,500, but large scope for more. Fees 2/6 upwards. Suitable house or flat can easily be obtained to meet purchaser's requirements. Rent of surgery on long lease £100 p.a. Premium 1½ years' purchase.
29. LANCS.—LARGE TOWN.—Very old-established good industrial class PRACTICE, producing £2,500 p.a., including panel of 1,804, and appts. worth about £120 p.a. Fees 2/6 upwards. Very suitable for two friends in partnership, as two houses available. Good sport and schools. Premium 1½ years' purchase. A one-half share will be offered with view to succession in six or twelve months if desired.
30. CHESHIRE.—Industrial Town within easy reach of Manchester.—Well-established PRACTICE producing £2,600 p.a., with panel of 2,870. Fees 2/6 to 3/6, medicine extra. Good house, with ample accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.

Full Schedule of Terms and Conditions will be forwarded on application.

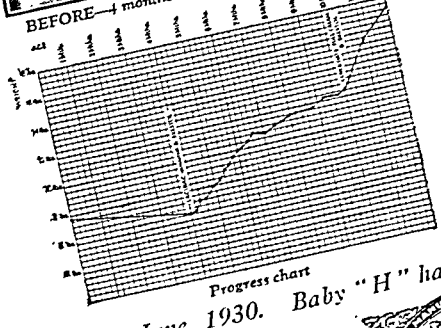
Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

NATURALLY RICH IN VITAMIN "D"



A "RESURRECTION"

THE mother of Baby "H" wrote to our Motherhood Bureau when he was 4 months' old (weight only 6 lbs 9 ozs.) suffering from Marasmus following Whooping Cough complicated by Double Pneumonia. The infant was put on to LACIDAC (Separated) with a small quantity of BRESTOL and immediately made steady progress.



At 6 months he had gained 3 lbs. 7 ozs. and by the end of another 4 months his weight was 12 lbs. 6 ozs., and progress was so good that it was possible to change him gradually on to Cow & Gate Full Cream and Brestol.

He has now cut teeth quite successfully and at the age of 10 months is taking normally to mixed feeding and is a happy, lively baby.

His Doctor considers him a 'Resurrection.'

BEFORE—4 months' old, 6 lbs. 9 ozs. in weight

Progress chart

AFTER—10 months' old, 12 lbs. 6 ozs. in weight

June, 1930. Baby "H" has now won a prize in a Baby Show!

Write for literature and clinical samples of Lacidac and Brestol

COW & GATE LTD.

Cow & Gate Milkfood

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—**It is effective.** It supplies the physiologically active calcium ion.

2.—**It shows distinct superiority** in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—**It enables physicians to adequately meet the requirements of any given case.**

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—**It is completely sufficient in itself as a therapeutic agent.**

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.

5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

teeth will result, although not as imperfect as would have been the case had the calcium intake been low.

So far only those food factors aiding calcification have been mentioned. One group of foods, however, is outstanding because it interferes with the deposition of calcifying salts in bones and teeth. Those foods are the cereals. There is a wide difference between cereals in this respect. For instance, so far as animal experiments are concerned, oatmeal is the worst of all examined, and white flour interferes least with the calcifying process. Intermediate between these are maize, rye, barley, and rice. The embryo or germ of wheat and maize, and probably of other grains, has this baneful effect more developed than the endosperm. The germ of rye has vitamin D (in small quantities) as well as the substance interfering with calcification, and these actions can be separated owing to the solubility of vitamin D in alcohol. In spite of great endeavour, it has so far proved impossible to obtain information as to the chemical nature of the substance responsible for this effect of cereals. It is not associated with the carbohydrate nor with the fat. There is a possibility that it is in some way bound up with a protein, but this is by no means certain. As regards this anticalcifying effect of cereals there is one point I should wish to emphasize, because I believe it is of local interest in Kenya. Much has been said in recent years as to the significance of the mineral content of the diet, and various diseases of cattle have been ascribed to deficiencies of these, especially of calcium, phosphorus, and iodine. Now I have stated that of all cereals and cereal products tested, oatmeal and grain embryo interfere most strongly with the deposition of calcium and phosphorus in bones and teeth. It is at the same time well known that these grain products are far richer in calcium and phosphorus than such a substance, for instance, as white flour. Thus we have foods which, while they contain a more abundant supply of Ca and P, may in the absence of sufficient vitamin D result in a smaller retention of these elements in the growing bones and teeth. In other words, a greater deficiency of calcium and phosphorus in the body can be brought about by diets which actually contain more of these substances, so that an analysis of mineral intake may be quite misleading as to the efficacy of a diet in adequately supplying these substances to the tissues.

It may be well to emphasize, however, that the calcifying effect of vitamin D, whether it forms part of the diet or whether it is supplied to the body as the result of the activation by sunlight of ergosterol in the skin, will always, if present in sufficient quantity, antagonize the anticalcifying effect of cereals. Thus, although the diet of the native is largely composed of maize, so long as his skin is unprotected from the sun's rays his bones and teeth will remain well calcified. If, in the course of his civilization, he adopts European habits of clothing, especially in childhood, then his bones and teeth may be as badly calcified as are those of the average European. On the other hand, when Europeans provide abundant vitamin D in the diets of their children, just so soon will their teeth and bones approximate in structure to those of the native as found at present.

Caries of the Teeth and Diet.

European teeth are generally badly calcified, and it would seem likely that this defective calcification is in some way related to caries. When teeth are well calcified, as in the average African native, they are white and shiny, and evenly arranged in powerful well-grown jaws. In the European only too often are the teeth discoloured, rough, and unevenly arranged. The following table gives an idea of the general relationship between the structure of teeth and susceptibility to caries in the case of English children.

The Relation of Structure to Caries in 1,036 Deciduous Teeth of English Children.

Teeth.	Defective in Structure.		Carious.	
Incisors	14.4 per cent.	.....	20.8 per cent.	
Canines . .	54.5 ,,	.....	46.2	,,
First molars .	73.1 ,,	.....	61.9	,,
Second molars .	91.9 ,,	.....	87.1	,,

The teeth were first examined for caries, and were then ground down to thin slices and their minute structure determined by microscopic examination.

It will be seen from this table (1) that both caries and defective structure are very common, (2) that the least defective in structure (the incisors) are the least carious, while the most defective in structure (the molars) are the most carious.

As a matter of fact, these investigations made by May Mellanby showed that, although on the whole there was a close relationship between the structure of the teeth and caries, this was not absolute, for there were about 10 per cent. exceptions.[3] Thus some teeth were imperfect in structure and yet free from caries, while others were good in structure and yet carious. The probable explanation of this was again brought to light by animal experiment. It is well known to all that teeth wear down as the result of attrition according to the degree of hardness of the food eaten. In response to attrition the teeth normally react by producing a layer of secondary dentine adjacent to the dental pulp. By this means the pulp is protected from direct exposure to the food. It was found in dogs that the type and amount of secondary dentine produced as the result of artificial attrition depended on the type of food eaten at the time. Thus a diet of high calcifying qualities resulted in abundant well-formed secondary dentine, while a diet of poor calcifying qualities—that is, one with deficient vitamin D and much cereal—produced either no secondary dentine or a poorly calcified type of this tissue. Now human teeth when attacked by caries also respond by producing secondary dentine, which may be abundant and well formed or deficient and badly formed. When the exceptions in the children's teeth were examined from the point of view of secondary dentine it was usually found that badly formed teeth (primary dentine and enamel) when free from caries had well-formed secondary dentine, while well-formed teeth with caries usually had badly formed secondary dentine. Thus it would appear that not only is the original formation of the teeth important as regards incidence of caries, but that, after full eruption and formation, teeth alter in their resistance to a bacterial onslaught according to the diet eaten. Thus a child may have a poor diet resulting in badly formed teeth, but at a later stage the calcifying qualities may improve and so increase the resistance of the teeth to caries. Similarly well-formed teeth may lose their resistance when the diet becomes defective, and so become more susceptible to caries. The final proof that this actually occurred in children was also demonstrated by May Mellanby and C. L. Pattison, who showed that even badly formed teeth attacked by caries could increase their resistance to such a extent that the carious process was delayed or even arrested if these children were given diets very rich in vitamin D (irradiated ergosterol).[4] This addition was made to the food of one batch of children, while another similar batch received the same food without the additional vitamin. The children receiving extra vitamin D not only showed great resistance to caries in the sound teeth as compared with the control children, but in many cases the actual caries was actually arrested. (Sections of teeth showing arrest of caries produced by vitamin D were shown on lantern slides.)

To sum up: Well calcified teeth can be produced by the ingestion of sufficient vitamin D during the formation of the teeth. (2) Well calcified teeth are less susceptible and badly calcified teeth are more susceptible to caries. (3) Independently of their original structure, the ingestion of sufficient vitamin D raises the resistance of teeth to caries and may even arrest the carious processes, while diets deficient in this substance, especially if they contain much cereal, allow a lowered resistance to caries and more rapid development of this condition.

Food and the Central Nervous System.

It has long been known that diet has a special relation to the peripheral nerves, and, in particular, that the anti-neuritic vitamin or vitamin B_1 is implicated in this relation. I do not, however, wish to speak on this point, but to describe some results we have obtained in Sheffield of

seem to show that diet has important effects on the central nervous system in quite another way. Some of these results are too recent to allow any definite deduction as to their practical or clinical significance, but they seem to me to be sufficiently suggestive to warrant description here.

In investigating the action of cereals on the formation of bones (experiments referred to above) we were impressed by the fact that some of the dogs developed severe incoordination of movement, often associated with and followed by weakness of the hind legs.[1] When the nervous system of these animals was examined histologically by Marchi's method a scattered degeneration of the cord was often found, of such a nature that it suggested a subacute combined degeneration. On attempting to track down the conditions associated with this degenerative change in the nervous system we found (1) that it most often occurs in animals receiving much cereal, and especially in those whose diet includes the germ or embryo of grains; (2) that it is only found in animals receiving a diet deficient in fat-soluble vitamins.

In order to come more closely to grips with the problem, recourse was made to the use of ergot in the diet. The fact that ergot of rye produces degenerative changes in the cord has long been known, for these changes have been described in human beings affected by nervous ergotism—a condition which is very fatal and appears in epidemic form occasionally in European countries where rye is the main type of cereal eaten. Many attempts have been made by previous investigators to produce nervous ergotism in animals, but the success obtained has been very irregular in all types of animals, and nobody has understood why such disagreement in general results should have occurred. Incidentally, the curious distribution of nervous ergotism in epidemic form has never been understood. On the whole, it attacks the poorer people in times of famine, but it picks out, apparently without any discrimination, some members of a family and leaves others untouched. We soon suspected the apparent reason for this, for degenerative changes in the cord do not depend only on the presence of ergot in the diet, but also on the absence of a protective agent of the nature of a fat-soluble vitamin, probably vitamin A or a closely associated vitamin. The protective agent was not vitamin D, for ergot itself was found to contain vitamin D. If, however, cabbage, which contains little or no vitamin D, or mammalian liver oil (rich in A but poor in D) was added to the diet, then ergot left the cord untouched. Other substances containing vitamin A, such as egg yolk, butter, or cod-liver oil, also prevent nervous ergotism in dogs. Vitamin D in the form of irradiated ergosterol will not in itself prevent the pathological condition. These results probably afford the explanation of the arbitrary way in which nervous ergotism develops in human beings. It develops in times of famine and distress because not only is the rye ergotized but poverty prevents the consumption of such protective substances as milk, eggs, and green vegetables. If, however, any individual has a good supply of vitamin A in the liver and other organs, the nervous changes will not be produced until these reserves are used up. It seems probable, therefore, that ergotism of the nervous system can be prevented in human beings by the inclusion in the diet of sufficient sources of vitamin A.

Having found that the degenerative changes in the cord in experimental ergotism were dependent on the absence of a protective dietetic factor, attention was again directed to the action of grain embryo and other cereals. It was found possible to produce the pathological condition by rye germ unaffected by the *Claviceps purpurea*. That is to say, that the nerve toxin in ergotized rye germ is present merely in exaggerated amounts as compared with normal rye germ. It has not proved possible, however, to obtain without fail the nerve degeneration by means of pure grain products in all dogs. Some litters have remained without obvious degenerative changes of the cord even when diet has included much wheat embryo and the vitamin A intake has been small. The negative results seem to depend on the litter of puppies and not on the specimens of wheat germ tested. What the explanation of this resistance in families is has not been ascertained. It may be that in some cases the maternal diet has been so good as to give the resistant litters a larger reserve of the protective substance (vitamin A) in their livers. Only further work will clear up this problem.

It may be said that, so far as the experiments can be interpreted, most cereals examined contain this toxic substance, even white flour, but there is much more in the embryo of the wheat, a fraction of the grain separated off in the manufacture of white flour. Oatmeal has also been found to contain this nerve "toxamin" (I have introduced the word "toxamin" to describe substances of unknown composition which have harmful effects in the body and which can be antagonized by specific vitamins. See also the anticalcifying toxamin referred to above, which can be antagonized by vitamin D.)

The question now arises, What is the clinical significance of these facts? So far as nervous ergotism in man is concerned the importance of the results described above is obvious. The three other conditions best recognized in which subacute combined degeneration of the cord arises are: (*a*) lathyrism, (*b*) pellagra, (*c*) pernicious anaemia.

(*a*) *Lathyrism.*—As regards lathyrism, I have had no experimental or clinical experience of the condition. It is a nervous disease often found on a large scale in the North-Western Provinces of India, and is apparently due to a diet containing a large proportion of lathyrus peas. Experiments have been carried out on animals by many people, including Acton,[2] Anderson, Howard, and Simonsen,[3] and Stockman,[4] but there is considerable discrepancy in the results obtained. It seems to me, on the analogy with the experiments quoted above on ergotism, that this discrepancy is probably due in part at least, to the same cause as that responsible for the irregularity of the earlier animal experiments on nervous ergotism—namely, that the nerve degenerative changes are dependent on a toxic substance in the lathyrus peas, but that the condition is prevented if there is a sufficiency of a "protective" substance in the other part of the diet. It may be the same protective substance as in nervous ergotism—namely, vitamin A—but this is only surmise at the present time. The whole picture of lathyrism, so far as I understand it, suggests, indeed, that the toxic agent of the lathyrus pea is of a similar nature to that of ergot nerve toxin: but this again is supposition. It is true that Stockman produced lathyrism in a monkey when the diet included "one ounce of fresh cabbage or a little fruit" daily, but fruit would be of no value as a protective agent on the hypothesis suggested, and the amount of cabbage was not only small but there is no statement as to how often this was given in the food and how often the fruit. The disease of lathyrism needs further investigation from this new angle.

(*b*) *Pellagra.*—It has been asserted that the later investigations of Goldberger on pellagra have cleared up completely the etiology of this disease. There is indeed no question but that so far as the skin lesions are concerned, Goldberger's work has definitely shown the importance of the pellagra-preventing factor now usually known as vitamin B$_2$. It is impossible, however, to consider the nerve degenerations in the cord of pellagrins together with the results above discussed on the effect of cereal and cereal products on the nervous system without wondering whether in pellagra also the degeneration of the cord is not associated with a "toxamin." The almost constant association of a maize diet with pellagra increases this probability. Is vitamin B$_2$, or the pellagra-preventing factor, the same substance as the protective substance against nervous ergotism and the cord degeneration produced by cereals in the experiments described above? Sources of the pellagra-preventing factor in Goldberger's investigations included milk, meat, and yeast. So far as milk and meat fat are concerned these are also sources of vitamin A, which I have shown is a protective substance against nervous ergotism. The one real discrepancy between Goldberger's results on pellagra and mine on nervous ergotism is that according to him yeast cures pellagra whereas it does not, in my work, prevent nervous ergotism. Yeast does not contain any vitamin A.

There has been no suggestion up to the present that there is a positive pellagra-producing factor in maize responsible for the cord degeneration, but the results under discussion suggest that pellagra is possibly due to a positive harmful factor in certain cereals, including maize, and that this factor is in normal people prevented from having its baneful influence by a protective agent of the nature of a vitamin or possibly vitamins, including B_2 and A. I have been unable to obtain degenerative changes in the cord by yellow maize. This may be due to the fact that it contains vitamin A, or rather carotine, which acts in the same way as vitamin A.

(c) *Cord Degeneration in Pernicious Anaemia.*—The close relationship of the cord degeneration found in pernicious anaemia and the changes produced by cereals in dogs in the absence of vitamin A suggests a similarity in etiology. There is a further coincidence which is in line with this point of view. Pernicious anaemia is brought under control by liver and water-soluble extracts of liver. The nerve degeneration of ergotism and that produced by wheat germ or embryo can be prevented or, if developed, the condition greatly improved by the fat-soluble portion of liver. In my experience the blood changes in pernicious anaemia cannot be cured by the fat-soluble portion of liver. On the other hand, it has been recently claimed by Ungley and Suzman[15] that the nerve symptoms of pernicious anaemia can be greatly improved by feeding whole liver. If so, it seems probable that it is the fat-soluble portion which exerts this effect on the cord. It is possible that both the blood changes and the cord degeneration in pernicious anaemia are due to failure on the part of the liver, the blood condition being due to the exhaustion of some specific water-soluble substance and the cord changes to a deficiency of a specific fat-soluble substance, maybe vitamin A as discussed above. Only further work will show whether pernicious anaemia has a positive dietetic causation similar to that found in cereals which produces nerve degeneration. It is interesting, however, to speculate, on the basis of the results described above, as to what extent these experimental methods of producing and preventing pathological changes in the cord by dietetic means will prove to be of practical value in aiding the solution of problems of disease commonly found in man.

The Prevention and Cure of Some Infective Conditions.

I wish now to pass on to another aspect of this subject of diet and disease. So far I have dealt with the production of pathological changes in various organs by substances actually present in food and the prevention of these changes by other "protective" food elements. I shall now deal with pathological conditions produced by the invasion of the body by certain micro-organisms and a method of preventing this invasion by specific dietetic means. This subject, again, is too new to allow any great claims to be made as to the extent of its possible application, but the results obtained seem to me to be sufficiently definite to warrant the belief that ultimately it will prove to be of great importance as a means of raising the resistance of the body to pathogenic micro-organisms and of gaining an insight into the subject of immunity.

Everybody who has been interested in the experimental side of dietetics and nutrition must have been struck by the susceptibility of animals to infection when eating defective diets. I called attention to this fact so long ago as 1919.[9] At a later stage I became more interested in the subject as the result of an experience in the laboratory in which a large number of experimental dogs died of broncho-pneumonia.[10] At the time my interest was particularly centred round bone calcification, but the incidence of the disease showed that the lung infection and the condition of the bones were independent, although both were related to fat-soluble factors. In other words, the susceptibility to lung infections did not depend on the absence of vitamin D, but probably on the absence of vitamin A. These results were published in 1926.[10]

More recently we have shown that young rats fed on a diet which, so far as is known, is complete except for vitamin A, die in the course of six to fifteen weeks, and on post-mortem examination are found to have developed one or more abscesses in different parts of the body. The relation of vitamin A deficiency to xerophthalmia has been known for many years, but our animals developed many other septic conditions, sometimes without any xerophthalmia. The more common seats of infection included the base of the tongue, the nasal sinuses, the middle ear, the lungs, the kidneys and bladder, the alimentary tract, and many other places. It was shown so long ago as 1922[11] by Mori that a peculiar effect of vitamin A deficiency is to produce various forms of hyperplasia of epithelium, and it is at these seats of hyperplastic change that the infective condition develops. More detailed facts of the relation of vitamin A to infection in rats and the history of the subject can be read in a paper published by H. N. Green and myself in the *British Medical Journal* in 1928.[12] It may be said that if sufficient vitamin A is given to these animals after having developed the infective condition recovery is often brought about. On the other hand, the inclusion of this vitamin in the diet prevents the development of the pathological state.

We were so impressed by the results of the animal experiments that Green and I determined to see whether vitamin A played any part in the resistance of the human body to infection. It seemed at first sight that this would probably be the case, because not only are the lesions produced in rats very common in people in England—for example, septic nasal sinuses, middle-ear disease, genito-urinary infections, and pneumonic conditions—but the diet in this country is largely cereal and notoriously deficient in vitamin A. The difficulty was to find a disease due to bacterial invasion the investigation of which would yield results, definitely positive or negative, in a reasonable time. Most common infective conditions recover in any case, and in pneumonia the results are variable whatever the treatment. We decided to study the action of vitamin A in puerperal septicaemia, a disease in which the mortality rate is normally so high that a rapid decision could be made as to the efficacy of the treatment. As a control series of cases we took those patients who had entered the institution where the investigation was carried out, in the two years prior to the new treatment. In these two years 22 patients had been admitted from whose blood a growth of haemolytic *streptococci* had been obtained. Of these 22 patients 20 died, giving a mortality rate of 91 per cent. From the beginning we have treated with vitamin A 9 similar cases, and of these 8 have made complete recoveries. There have also been two other septicaemic patients, one with an infection of *Bacillus coli*, who recovered, and the other with a staphylococcic infection, who died. Thus, of the total 11 cases, 2 have died, giving a mortality rate of 18 per cent., as compared with the mortality rate of 91 per cent. in the control group. The results can be readily seen in the following table.

Type of Blood Infection.	Control Group of Cases.			Vitamin A Treated Cases.		
	No.	Deaths.	Mortality Rate.	No.	Deaths	Mortality Rate.
Haemolytic Streptococci	22	20		9	1	
Bacillus coli	0	0		1	0	
Staphylococcus ...	0	0		1	1	
Total ...	22	20	91%	11	2	18%

It is true that the number of cases treated with large doses of vitamin A is not sufficiently great to allow of a definite claim that this substance is a specific remedy for puerperal septicaemia. Nor were the cases of the intense fulminating type sometimes met with in this condition. On the other hand, we think there is strong evidence, especially taken in conjunction with the animal results, that vitamin A has a definite effect in raising the resistance of the body, both human and animal, to bacterial agencies, and that, in its absence from the

deficiency in the body, the resistance to infection of this type is greatly diminished. It is obviously necessary that this work[13] should be repeated on a larger scale and extended to the treatment of other infective conditions, for its practical importance, if established, cannot be exaggerated.

What value these results, if established, may have to medical men in Africa is for you to determine. They may point to a method of reducing the high mortality rate in pneumonia among the natives as well as among Europeans. If it does act curatively in this condition, the probability is greater that the inclusion in the normal diet of sufficient quantities of vitamin A will prevent the disease as well as other infections of a similar bacterial nature. Rich sources of vitamin A are egg yolks, mammalian liver, cod-liver oil, and there is some in carrots, green vegetables, milk, butter, and suet. It may be well to add that vitamin A is a very unstable sub-tance and is apt to disappear rapidly, especially in high concentrations.

I have endeavoured to supply you with evidence, both experimental and clinical, which shows how important is this subject of the relation of diet to di-ease. In particular, I have tried to demon-trate that food includes both harmful and protective constituents. In so far as the harmful substances mentioned are in the food itself, it appears that they can be neutralized in their action by the protective agencies. The protective agencies are of the nature of vitamins, and the two I have specially dealt with are vitamins A and D. The harmful factors are mostly associated with cereals and cereal products so far as present knowledge goes.

I wish especially to emphasize that this subject is only in its infancy, and that many of the facts I have dealt with here have still to be investigated more closely, partly because it is impossible as yet to decide what is their true clinical significance, and partly because there is no knowledge of the methods by which these substances exert their effect. So far as you in Kenya are concerned, it seems to me that these dietetic problems, especially those concerning the toxic action of cereals, may have special significance, for I cannot believe that your native population with its high cereal diet completely escapes those effects. It is true that the sun-shine to which the African native exposes himself mu-t tend to neutralize the anticalcifying effect of maize by supplying vitamin D, but I should expect the natives who wear European clothing, especially in childhood, and remain on his maize diet to suffer accordingly. Similarly it seems to me probable that a deficiency of vitamin A might be present in many native diets especially in the towns, and that pathological results would follow. I shall be interested to hear of any investigations which may be made in the future to see whether these hypotheses have a bearing on any of the problems of disease in Africa.

A British Medical Association Lecture on CORONARY OCCLUSION.

DELIVERED BEFORE THE HARROGATE DIVISION, NOVEMBER 30TH, 1929,

BY

CRIGHTON BRAMWELL, M.A., M.D., F.R.C.P.,

ASSISTANT PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

IT is only recently that the subject of coronary occlusion has attracted the attention of clinicians in this country. Until a few years ago it had generally been regarded as of purely pathological interest, as one of the possible causes of sudden death; but we now know that many of these patients survive, and that the symptom complex is often so clearly defined that the diagnosis during life presents no difficulty.

INCIDENCE.

The condition is by no means rare. During the past two years I have seen 23 cases in private practice. This series,* though small, will, I think, suffice to illustrate most of the clinical features to which I wish to refer. I shall also include one other case (Case 1) which presented certain points of special interest. Both the sex and the age incidence in my series agree fairly closely with that reported by other workers.

The preponderance of males over females suggests that mental and physical strain may be important etiological factors. The age incidence coincides with that of the degenerative period of life, and this is what might be expected, since neither syphilis nor rheumatic infection appears to play any significant part in the etiology. It is curious that syphilis is not a more common cause of coronary occlusion, since the first part of the aorta is so frequently involved.

*This series is one of several groups of cardiac cases the after-histories of which are being followed up on behalf of the Medical Research Council.

TABLE I.—*Age and Sex Incidence.*

	Bramwell	Levine[3]	Parkinson and Bedford[4]
Age.			
Over 70	7	14	19
50–69	17	99	68
Under 50	6	12	23

Male	18	111	93
Female	6	14	7
Total	24	125	100

CLINICAL FEATURES.

Let me begin by recounting the clinical findings in two typical cases.

CASE I.

A man aged 53, who had always lived an exceptionally healthy and abstemious outdoor life, after a hurried lunch rose to play golf. When walking downhill to the sixth green he experienced a sense of fullness and discomfort in the chest. At the top of a hill which was an uphill slope, his discomfort increased and he had to give up and walk home. The pain spread down the left arm to the little finger, and continued to increase in severity in spite of his going to bed. His doctor saw him at 4 p.m., and gave amyl nitrite and a quarter of a grain of morphine. This, however, failed to bring any appreciable relief. The pain persisted during the night it began to involve the other arm, and it was not until the following afternoon that it became easier and gradually passed off.

When I saw him, ten days later, although he had had no recurrence of the pain since the day following the attack, he still looked extremely ill and careworn. He walked and behaved like an old man, obviously afraid that the least exertion might precipitate another attack. On physical examination the heart was slightly enlarged. The second sound was unduly resonant in the aortic area. The retinal arteries showed atheromatous changes. The blood pressure was raised (systolic 160, diastolic 105). The urine contained

albumin. The electro-cardiogram (Fig. 1)* showed the characteristic features associated with coronary thrombosis; but an *x*-ray examination, beyond confirming the presence of cardiac enlargement, revealed nothing abnormal.

Nearly three years have now elapsed since his attack. During this period he has had no recurrence. Nevertheless he has been compelled to take things quietly, for if he attempts to walk briskly uphill he gets what he describes as a "warning shadow" of the pain in his chest. His blood pressure, when I saw him two months after the attack, had risen to *190/115*. *It is now 220/130.*

In this case I wish to call attention more particularly to two points. First, to the fact that the patient was a man of exceptionally good physique who had lived a careful life, and believed himself to be in perfect health up to the moment that his pain commenced. Except for an operation for gall-stones three years previously he had never had any serious illness. Levine,[3] in his comprehensive survey of the subject, goes so far as to say that

"The typical patient is a well-set person, somewhat overweight, often of considerable physical strength, who enjoyed unusually good health. Such patients often have indulged in vigorous physical efforts either in the form of sport or in their ordinary work."

Secondly, I wish to dwell on the character of the pain itself. Pain such as I have described in this case differs from the pain of an ordinary anginal attack. Instead of passing off in the course of a few minutes, it lasted for many hours. The pain was not relieved by rest; in fact, for a time after the patient got home it actually increased, both in intensity and in the extent of its distribution. The pain was not relieved by nitrites, and only partially by morphine. Unlike angina, the pain of coronary thrombosis is just as liable to come on when the patient is resting. In several of my cases the attack occurred when the patient was lying quietly in bed at night, or before getting up in the morning. This is in striking contrast to the typical anginal attack, which is brought on by exertion or emotion, and relieved by rest. Further, instead of remaining absolutely motionless and afraid to move during the attack, the patient often tosses or walks about, for he discovers that rest does not relieve the pain.

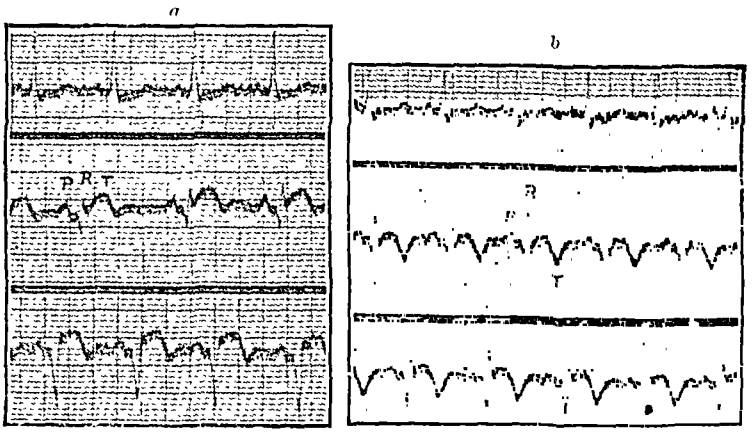

FIG. 1.—Two records taken from Case i on March 28th, 1927 (*a*), and May 16th, 1927 (*b*), showing change in form of ventricular complex.

Most frequently, in my series, the pain started either at the level of the lower end of the sternum, or in the epigastrium, though in one case it was first felt in the jaw, and in another in the region of the larynx. It often spread right across the chest. It varied greatly in intensity, and in the milder cases was sometimes described as a feeling of tightness and discomfort which prevented the patient taking a deep breath. The pain often spreads down the left arm, and in six of my cases the right arm was also involved.

CASE II.

A gardener, aged 70, who had never had occasion to consult a doctor, though he had been somewhat short of breath for about twelve months, was walking to his work, a distance of half a mile, one Thursday morning, when he suddenly experienced a sharp pain, strictly localized to a small area in the middle line at the level of the lower third of the sternum. The pain passed through to the back, but did not radiate to other parts of the chest nor to the arms. The day was windy, and he was walking uphill when the pain came on. He rested and returned home, having to stop at intervals on the way to obtain relief. On reaching home he vomited. After resting the pain gradually passed off. He had some lunch at noon, and felt sufficiently well to go back to work. On the way he experienced slight discomfort in the same position as before. When he had almost reached his destination the severe pain came on again, and again he vomited. He took things quietly for the next couple of hours, and the pain "mended" a little. About 3 o'clock, however, whilst he was potting some plants, it became worse, and he went home to bed at 6.30. His doctor saw him shortly afterwards, and found him collapsed and vomiting watery fluid. The liver was enlarged and very tender. The pain and vomiting continued all night. On Friday the pain was easier, and by midday it had quite passed off. On Friday and Saturday his temperature was slightly above normal; and on Sunday morning he coughed up a little blood.

When first I saw him, at noon on Sunday, his pulse was barely palpable, and he had auricular fibrillation, with a heart rate of 160. The blood pressure was about 110/90. The liver was still slightly enlarged and very tender, and there was some general rigidity in the abdominal muscles. He was lying flat in bed, and there was no dyspnoea.

On the following Thursday—a week after the attack—he was admitted to hospital. In the interval there had been no recurrence of the pain, and his general condition was much improved. The pulse was now quite strong and regular, the heart rate being 96 and the blood pressure 135/95. The electro-cardiogram showed ventricular deflexions of low voltage with a large negative T wave in Lead III. Examination of the blood showed a leucocytosis of just over 10,000, with excess of polymorphs.

On Sunday, when his wife came to visit him, she remarked how well and cheerful he was. About 6.30 the following morning, however, when the nurse went to make his bed, she thought at first he was asleep, but found that he was unconscious and cyanosed, with Cheyne-Stokes respiration. The radial pulse was not palpable. She administered a stimulant, and his condition had already improved when the house-physician arrived a few minutes later. His pulse was then quite good, 70 and regular, though he had not regained consciousness. When doing his morning round at 10.30 the house-physician noticed that he had again collapsed, never having completely regained consciousness in the interval. He died a few minutes later. Post-mortem examination showed *that death was due* to rupture of the ventricle at the site of the infarct.

This case serves to illustrate certain other features which are highly characteristic of coronary occlusion. The attack is frequently accompanied by intense shock and prostration, due to a sudden fall in blood pressure. This is obviously a very different state of affairs from the ordinary anginal attack, in which, if the blood pressure changes at all, it tends to rise. In an anginal attack the rate and rhythm of the pulse remain unchanged, whereas after a coronary thrombosis the patient may be pulseless, or, if the pulse be palpable, it is often very rapid or irregular. There is frequently a combination of pallor and cyanosis, which gives to the face a peculiar appearance.

Quite apart from the character of the pain and the shock and collapse associated with it, however, there are other features which serve to differentiate coronary occlusion from true angina. As in this case, vomiting often accompanies the pain. It is a symptom which is apt to be misleading, for when the pain is confined to the epigastrium, as is not infrequently the case, the condition closely simulates an acute abdominal emergency. The presence of abdominal rigidity helps to reinforce this impression. The abdomen has often been opened in error in cases of coronary occlusion. This is perhaps hardly surprising, for without an electrocardiogram the differential diagnosis may occasionally be very difficult. The occurrence of dyspnoea should arouse suspicion, for when epigastric pain, vomiting, collapse, and abdominal rigidity are associated with dyspnoea, in a patient past middle age, the possibility of coronary occlusion should always be considered.

Coronary thrombosis not infrequently occurs in patients who have previously suffered from ordinary anginal pain, though, as in Case i, it may come "like a bolt from the blue" to a man who had apparently been in perfect health up to the moment of the seizure. Very rarely, however, a patient who has previously suffered from angina

* All the electro-cardiograms in this paper were taken with a string galvanometer of 2 cm. = 1 mv.

develops coronary occlusion, he generally realizes at once that this attack is something quite different from what he has previously experienced. In 8 of the 24 cases in my series the cardiac infarction had been preceded by ordinary anginal symptoms.

Another sign of diagnostic value is transient pericardial friction, which may be heard over the site of the infarct. I met with this sign in three only of the cases in the present series, but it is probable that the true incidence is really considerably higher, for friction may disappear in a few hours, and often I myself only had the opportunity of examining the patient once, and that not until several days after the attack.

Atypical Cases.

When pain is not a prominent symptom the diagnosis is apt to present more difficulty. In the two following cases in my own series I should have been in doubt as to the diagnosis had it not been for the electro-cardiographic findings.

Case III.

An unmarried woman, aged 50, was sent to see me by one of my gynaecological colleagues whom she had consulted on account of amenorrhoea, under the impression that her symptoms might be due to the menopause. She gave a peculiar history, that for precisely one week she had suffered from tightness in the chest and dyspnoea on exertion. It was difficult to account for the sudden onset of these symptoms, and no cross-examination would shake the patient as to the date of their appearance.

On examination the heart was considerably enlarged. The blood pressure was 250/130; the resting heart rate was 120, with typical gallop rhythm. The electrocardiogram afforded the explanation of the unusual history, the features being characteristic of coronary occlusion.

This patient kept surprisingly well for eight months after I saw her. Subsequently, however, she became extremely emotional, and spent a large part of her time weeping, a mental state which I have noted in two other cases, and am inclined to attribute to the associated cerebral arterio-sclerosis.

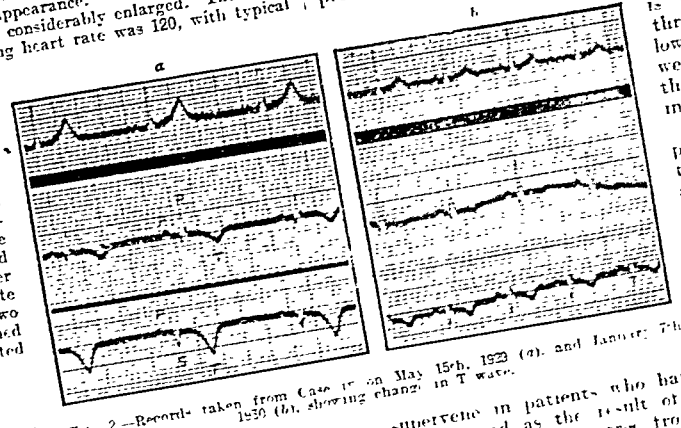

FIG. 2.—Records taken from Case iv on May 15th, 1929 (*a*), and January 7th, 1930 (*b*), showing change in T wave.

Case IV.

A commercial traveller, 40 years of age, who to the best of his knowledge had previously been in perfect health, was endeavouring to start his motor car one cold morning. He struggled with it for nearly half an hour, and then had to give up on account of dyspnoea and some discomfort in the chest. After resting a quarter of an hour he felt better, and tried again. This time he stuck it for about a quarter of an hour and again collapsed exhausted, the pain being more severe. His doctor, who saw him shortly afterwards, thought that he was going to die. He was intensely cyanosed and shocked. The pulse was barely palpable. All the following day the heart was extremely irregular, but normal rhythm was restored forty-eight hours later, and it was not till then that the pain passed off.

When I saw him four days later the slightest movement provoked respiratory distress, and he still complained of a good deal of pain in the left chest, passing through to the angle of the scapula. His heart rate was then 54 per minute, and the blood pressure only 85/50. He was admitted to hospital five days later, and the electrocardiogram shown in Fig. 2*a* was taken.

In this case it was difficult to account for the sudden onset of heart failure in a man who, up to the time of his attack, had apparently been in good health.

Differential Diagnosis.

Coronary occlusion is apt to be mistaken for various other conditions. To two of these I have already referred in some detail—namely, ordinary angina and the acute abdominal crises such as perforated peptic ulcer, acute cholecystitis, and acute pancreatitis.

An erroneous diagnosis of diabetic ketosis is not unknown. This is perhaps less surprising than might appear at first sight, for not only is transient glycosuria a common manifestation after an attack, but coronary occlusion not infrequently develops in patients suffering from true diabetes. Levine noted the presence of glycosuria or actual diabetes in 34 of the cases in his series, and two of my patients were diabetics. Lastly, those patients who develop pulmonary oedema with moist sounds at the bases of the lungs are sometimes thought to be suffering from pneumonia, and it is important to remember that in some cases dyspnoea, not pain, is the principal symptom.

Blood Pressure.

When one comes to analyse the blood pressure readings in these cases, one cannot fail to be struck by the figures obtained.

TABLE II.—*Blood Pressure.*

	Cases	Died
Normal values	3	1
High systolic (180 or over) after attack	7	1
High systolic (200 or over) before attack	3	0
Low systolic (110 or under)	7	3
High pulse pressure (both had aortic incompetence)	2	1
Low pulse pressure (150 115 and 140 110)	2	2
Total	24	11

It is interesting to follow up the after-histories of patients who had hypotension when I first saw them. Of the seven, three have died. In the remaining four cases the blood pressure subsequently attained the normal level, though in one case (Case iv) it took eight weeks to do so. It is noteworthy that the three cases with the lowest readings all did well. They were the three youngest patients in my series.

A considerable fall in pressure at the time of the infarction is the rule, and in some of the cases where prior to the attack the pressure was high, it never again attains its former level. This may be advantageous to the patient, for, as I have already mentioned, coronary occlusion is apt to supervene in patients who have previously suffered from angina, and as the result of the fall in pressure these patients may remain free from anginal attacks after the coronary thrombosis. On the other hand, there is a less fortunate group—patients who prior to the thrombosis had enjoyed good health, and who after the attack suffer from paroxysms of ordinary angina.

TABLE III

Blood Pressure when first seen	Age.	Sex.	Subsequent Readings.	Remarks.
105/65	50	F.	135/95	Fairly well 20 months.
110/90	70	M.	155/95	Died, ruptured ventricle (Case ii).
110/90	58	M.	—	Died three months after attack.
110/90	71	F.	—	Died in attack.
85/50	40	M.	160/85, 120/75	Well, working 7 months (Case iv).
80/60	57	M.	122/75, 140/90	Well, working 12 months (Case v).
Not obtainable	59	M.	155/95	Convalescent 2 months (Case vi).

Electro-cardiographic Findings.

I have already referred to the fact that certain changes occur in the electro-cardiogram in many, though by no means in all, cases of coronary thrombosis. Let me now amplify this point.

In 18 cases in my series I was able to obtain an electro-cardiogram. One case had right branch bundle-block, and another incomplete bundle-block. Eleven exhibited certain special features which are of peculiar interest and importance, for it has been shown by Smith[5] that they can be produced experimentally in the laboratory by ligature of one of the coronary arteries. In health the form of the electro-cardiogram remains remarkably constant in any one individual. After myocardial infarction, however, striking changes occur. The T wave starts before the initial rapid ventricular deflexion has returned to its base line. It "takes off" at an abnormally high level. Or perhaps it would be more accurate to say that the R–T interval becomes convex. In its extreme form this type of ventricular complex is absolutely pathognomonic of myocardial infarction, though minor degrees of variation from the normal, in which the T wave takes off slightly above the base line, have been met with in other conditions. Levine[3] has published records from cases of pneumonia and uraemia which exhibit this peculiarity, and Hoogerwerf, Ellis, and I[2] obtained similar records from athletes who were competing in the Olympic Games at Amsterdam. As time goes on the record again changes, the T wave becoming negative (Fig. 1).

Another curious feature in many of these records is seen in Lead III, where the initial ventricular deflexion is of large amplitude and of negative sign (Figs. 1 and 3). This

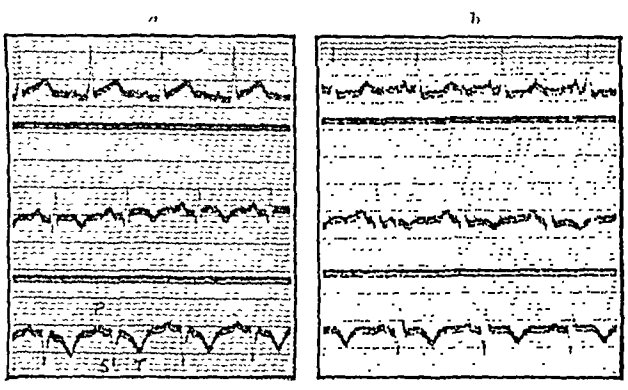

FIG. 3.—Records taken from two cases in present series showing characteristic form of ventricular complex with large negative T waves and initial negative deflexion in Lead III.

feature is not peculiar to coronary thrombosis; I have seen it occasionally in records from patients with old-standing high blood pressure.

PROGNOSIS.

There is perhaps no disease in which an accurate prognosis is more difficult than in coronary thrombosis. Eleven of my 24 patients have died, 3 from the effects of shock in their first attack, and 3 others in subsequent attacks. Those patients who survive their first attack are liable to have further attacks, any one of which may prove fatal. Hence the possibility, if not the probability, of sudden death must always be borne in mind in framing the prognosis. Sudden death in these cases is probably due to ventricular fibrillation. In patients who escape this fatality, the profound shock associated with the infarction is the most grave immediate danger. One should not, however, despair of recovery even in those cases which are most profoundly shocked. The most extreme example I have seen was the following.

CASE V.

A mechanic, aged 39, who had previously been in good health, rushed out one evening after a hurried meal to play in a tennis tournament. During the game he became dizzy, collapsed, and cyanosed. He managed to struggle home. When his doctor saw him his temperature was 95°, and he was intensely shocked and collapsed, and complaining of pain across the lower part of the chest. His pulse was 140. He vomited at the commencement, and several times subsequently. The following morning he developed a loud pericardial rub, and when I saw him, eighteen hours after the onset of his illness, he was still clammy and collapsed. No pulse could be felt in the radial or in the brachial arteries. The heart rate was 228, and its rhythm regular. Pericardial friction was audible all over the precordium. He appeared to be on the verge of death. For the next twenty-four hours his condition seemed hopeless, but on the following morning his heart rate suddenly dropped to 70, and he began to show signs of rallying. He then gradually improved, though it was not until ten days after his attack that he became fully conscious of his surroundings. Three months later he was sufficiently well to be brought up to London for re-examination.

Since seeing this patient I have hesitated ever to give an absolutely hopeless prognosis in coronary occlusion, no matter how desperate the condition of the patient might appear. In those patients who get over the initial stage of shock there still remains the danger of rupture of the heart. This complication may arise most unexpectedly, as in Case ii in my series. Though rupture generally occurs within a fortnight of the infarction, it is probable that cicatrization of the scar is not complete for another three or four weeks. For this reason alone the importance of complete and absolute rest during the early weeks of the illness is apparent. In a considerable percentage of cases death results from progressive heart failure of the congestive type, with or without auricular fibrillation. Three of my four deaths in my series were due to this cause.

Finally, there is one other accident which merits attention—namely, embolism. When infarction has taken place a mural thrombus forms on the infarcted area. Portions of this thrombus are liable to separate off and give rise to embolism in the brain or elsewhere.

During and immediately after the attack prognosis is exceedingly difficult. There does not appear to be any one symptom or sign which affords a reliable guide. The degree of the initial shock and the extent of the fall in blood pressure might be expected to indicate the ultimate prospect, but, as I have already pointed out, this is not invariably true; some of the most desperate cases make a truly surprising recovery. There is, however, in this connexion one finding which in my experience is of great significance—namely, the presence of a high diastolic associated with a low pulse pressure. As I have pointed out elsewhere,[1] I regard the systolic pressure as a measure of the heart's capacity to meet its liabilities. A high diastolic pressure greatly impairs the elasticity of the arteries. It increases the heart's liabilities, and necessitates a considerable elevation in the systolic pressure if the cardiac output is to be maintained. In these circumstances a fall in systolic pressure means a diminished output and a failing heart muscle.

On the optimistic aspect I am inclined to think that the age of the patient should be regarded as a factor of considerable importance. My three youngest patients are interesting. They were all very severe cases, and all three have done unexpectedly well. To two of them (Cases iv and v) I have already referred. The history of the third is as follows.

CASE VI.

An estate agent, aged 37, was suddenly seized with severe substernal pain while still in bed one morning. His doctor found him intensely collapsed, ashen in colour, and pulseless. He vomited. The pain spread to the region of the cardiac impulse and down the inner side of the left arm. By 11 a.m. it had become very severe, but was still present on the two following days, in spite of repeated injections of morphine. Nearly a fortnight after a pericardial friction was noticed for the first time, to the right of the sternum. It was only present for about twenty-four hours. It was accompanied by a slight rise in temperature. On the day of the attack the systolic blood pressure was 80, but when I saw him a fortnight later it had risen to 120, with a diastolic pressure of 75, though the first heart sound was still barely audible at the apex. The superficial vessels were not thickened, but his retinal arteries were unduly tortuous. An electro-cardiogram taken two months later showed a P–R interval of more than 0.2 sec. with a small wave in the ventricular complexes immediately preceding the rapid deflexions. The heart's rhythm remained regular throughout.

The patient's doctor now informs me that he has had no recurrence of the pain since his original attack, twelve months ago, and is able to attend to most of his office work, and to drive his car. In fact, he is remarkably fit.

This patient was a very heavy smoker, and admitted to fourteen ounces of tobacco a week. It seems possible that excessive smoking may have played some part in producing his arterial degenerative changes. On the other hand, there was a familial tendency to arterial disease, for his uncle died of angina at the age of 30, and his father

a heart attack in the forties. The patient himself, though otherwise healthy, had always been somewhat short of breath on going uphill.

TREATMENT.

I know of no drug but morphine which will relieve the pain of coronary thrombosis, and it must be given freely. A quarter of a grain is generally insufficient, and my own practice, in severe cases, is to give an initial dose of half a grain hypodermically. When the blood pressure is low active stimulation is indicated, and apart from the relief of pain the treatment resolves itself into that of "shock"—keeping the patient warm, raising the foot of the bed, giving brandy or other stimulants by mouth, and camphor subcutaneously. I have tried ephedrine in some cases, but am not fully convinced of its value. Measures such as these may tide over the danger period. Let me repeat that, if there is one group of drugs more strongly contraindicated than any other in these cases, it is the nitrites. Continuous oxygen inhalation may be helpful when oedema of the lungs is present, though it cannot be expected to do good when the cyanosis is attributable solely to a diminished cardiac output.

The rapid heart action associated with auricular fibrillation, or paroxysmal tachycardia, which sometimes complicates coronary thrombosis, may in itself endanger life. In the former digitalis given by the massive dose method of Eggleston or intravenous strophanthin is called for; while the only drug which seems to have any effect in arresting the paroxysms of tachycardia is quinidine; six grains may safely be given, and repeated, if necessary, at two-hourly intervals for five doses.

To the importance of complete rest I have already referred. After a severe attack of coronary thrombosis the patient should not be allowed even to sit up in bed for two or three weeks.

CONCLUSION.

In the short time at my disposal I have only attempted to deal with the more important practical points in connexion with coronary occlusion. I have endeavoured to show that the study of coronary thrombosis is not confined to the post-mortem room. It is a definite clinical entity, which, in a large percentage of cases, can be recognized with certainty during life. Its recognition is important, because many of the patients survive, and a few are sufficiently restored to health to resume their former occupations. Further, a correct diagnosis is of vital importance, not merely in framing the prognosis, but also in determining the treatment. An acute coronary occlusion may closely simulate an abdominal crisis, and if unrecognized may be submitted to laparotomy, which, in view of the cardiac lesion, is almost certain to prove fatal. Other cases are mistaken for ordinary angina and treated with nitrites—a dangerous procedure in view of the low blood pressure.

The crescendo character of the pain, its duration, the fact that it is not relieved by rest and that the attack frequently occurs when the patient is resting and is in no way attributable to exertion, are important. The fall in blood pressure, the shock, prostration, and vomiting which generally accompany the pain, serve to distinguish it from true angina, as do the feeble first heart sound, the gallop rhythm, the rapid pulse, and the pericardial friction which are sometimes present. I need hardly say that one must not expect to find all these signs in every case, but there is generally ample evidence, even without the electrocardiograph, which, if it be available, will often clinch the diagnosis.

The aspect of prognosis is so difficult that I almost hesitate to refer to it, though my own experience would lead me to believe that even the most desperate cases may recover, especially when the patient is under 50 years of age.

THE CORONARY ARTERIES IN A CASE OF FAMILIAL LIABILITY TO SUDDEN DEATH.*

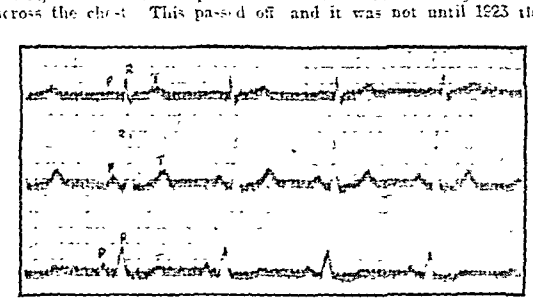
BY

C. E. K. HERAPATH, *M.C.*, M.D.,
ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY;
AND
C. B. PERRY, M.D., M.R.C.P.LOND.,†
MEDICAL REGISTRAR, BRISTOL GENERAL HOSPITAL; PHYSICIAN TO OUT-PATIENTS, BRISTOL HOSPITAL FOR SICK CHILDREN.

WE publish the following record in the hope of eliciting from others, and especially from family practitioners of long experience, notes of similar cases.

In 1924 Carey Coombs and J. J. S. Lucas described to the Association of Physicians a family of whom the father and two sons had died with great suddenness. They had examined the heart of one of these sons, a man aged 32, who had been taken ill while playing football and had died within an hour or so; it was found to present macroscopical changes apparently of an atheromatous type in the coronary arteries. These changes had not been histologically examined as the specimen had been lost. They also gave particulars of a third son who had been seen by them for symptoms suggesting angina pectoris.

This man was first seen in 1923. The history was that in 1918, during exercise, he complained of an uncomfortable tight feeling across the chest. This passed off and it was not until 1923 that



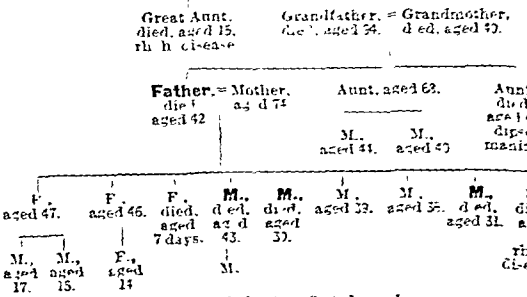


FIG. 1

the attacks became at all frequent. He then stated that for the previous ten months the attacks had been getting more frequent, and were brought on more and more readily, till in the latter part of the year he could not run ten yards without experiencing a tight gripping sensation in the chest. He never became dyspnoeic because the feeling came on before he had time to get out of breath. It never occurred at night, but was more easily brought on after a meal.

In May, 1925, one of us (C. E. K. H.) was asked to take an electro-cardiogram. (See Fig. 1.) The following is a genealogical tree of the family.

Heavy type indicates affected members.

In October, 1927, the patient was sent to see one of us (C. E. K. H.). He stated that the attacks were now associated with pain. A sudden tight feeling over the sternum was associated with an acute pain in the same region which was quite stationary,

FIG. 4.—Radiograph of a normal injected heart of the same age, showing the "age change" occurring normally, for comparison.

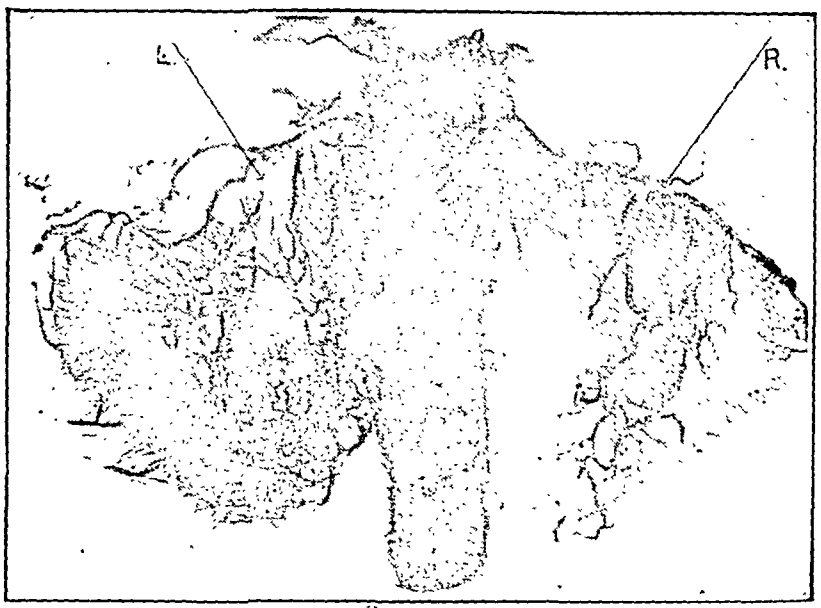

FIG. 5.—Radiograph of the injected heart opened out, showing obstructions in the coronary circulation and the increased vascularity of the left ventricle.

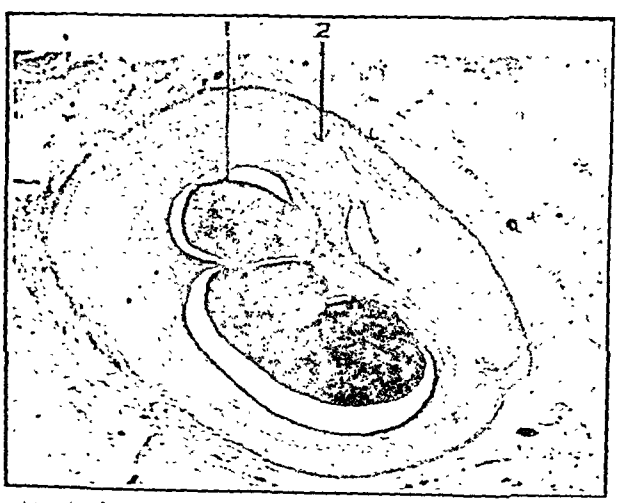

FIG. 6.—Low power photomicrograph of one of the larger [illegible] showing (1) the [illegible]

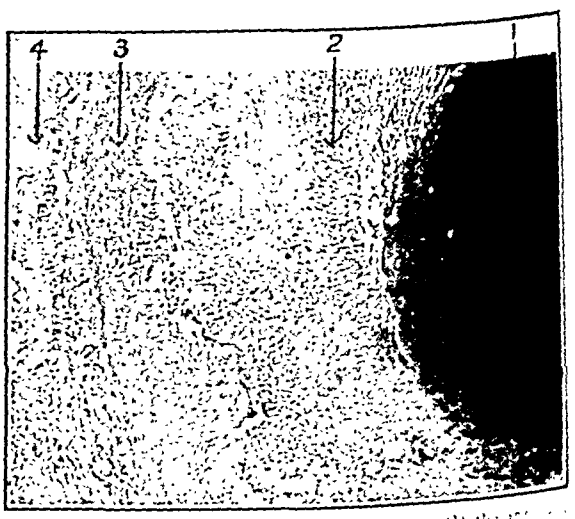

FIG. 7.—Higher power view of same, showing (1) the [illegible] mass; (2) the thickened intima; (3) the media; (4) [illegible]

and he felt bound to stand still for a few minutes, after which he was able to carry on again. The pain had never occurred at night, but was definitely produced more easily after food. The attacks had gradually got more frequent, though not more severe, and the exercise of quiet walking was sufficient to bring one on. Latterly he had had two or three attacks a day.

On physical examination the heart was not enlarged. An *x*-ray outline was taken, and this showed a heart of normal shape, but the aortic shadow was wider than normal. The heart sounds were clear, though the first sound was rather high-pitched; the aortic second sound was not accentuated. The arteries were not thickened, and the blood pressure was 120/70. The urine was normal, the Wassermann reaction negative, and no abnormal signs were present. Another electro-cardiogram was taken (Fig. 2), and this showed a marked difference in the "T" complexes.

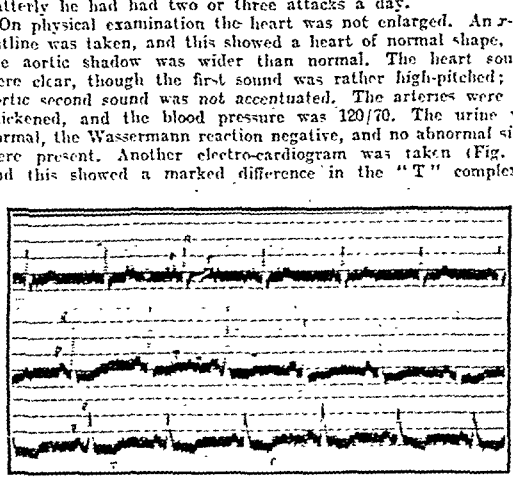

FIG. 2.

Whereas in the former one all the T's were positive, in this second one T2 is barely positive and T3 is definitely negative.

A month after this examination he fell down dead when getting into a tram-car.

Post-mortem Examination.

The post-mortem examination was performed at the Bristol Royal Infirmary by Dr. A. D. Fraser, and by his kindness one of us (C. B. P.) was able to examine certain organs in detail.

The subject was a well-nourished male about 40, and there were no external evidences of trauma or of disease. The lungs were normal in appearance, as also were the abdominal organs, with the exception of the aorta and kidneys. The aorta in its thoracic part showed slight atheroma, but the atheromatous change was very marked in the abdominal portion. There were several atheromatous ulcers, and in one or two places calcification had occurred. On section the aortic lesions show pronounced intimal thickening. In most places the media is the seat of replacement fibrosis. The intimal lesions in some parts show extensive fatty degeneration, and around the fat deposits are a certain number of mononuclear cells with a foamy cytoplasm, apparently engaged in phagocytosis of the fat. This is the only cellular reaction to be seen in the lesion.

The heart was somewhat enlarged, and on palpation the coronary arteries were definitely hard and thickened. It was injected with a barium gelatin emulsion, through the coronary arteries, according to the technique described by Gross,[1] and *x*-ray photographs were taken.

The skiagram of the injected heart shows intense vascularization of the left ventricle. This increase in vascularity of the left side compared with the right corresponds to a very extreme degree of the "age change" described by Gross, although in this case it is much more marked than one would expect at twice the age. At the age of 40 the increase of the blood supply of the left ventricle over the right is normally only just becoming obvious. In both the right and left coronary areas there are obstructions to the circulation.

All four valves were normal in appearance. On microscopical examination the myocardium shows areas of dense fibrosis. The coronary arteries are in many places almost completely occluded by massive intimal thickening, similar in type to that occurring in the aorta. In places this intimal thickening has been vascularized by new capillaries. Both internal and external elastic laminae are, in places, broken up, and the media shows some increase in the amount of fibrous tissue it contains. There appears to be some increase in the adventitial layer of fibrous tissue.

The kidneys were normal in size and appearance. There was very little abnormality in the small renal vessels; the renal artery shows medial fibrosis, but no intimal change.

The cause of death would appear to have been impairment of the coronary circulation due to degenerative changes in the coronary arteries. The pathological process corresponds with that of a premature senility of the arterial tree, with a particular incidence on the coronary arteries. There is no evidence of any infective factor. The pathology of the coronary artery lesions resembles that in the case described by Perla and Seligman,[2] except that in their case the lesion was by no means confined to the coronary arteries.

We may also refer to a recent paper from this laboratory in which Hughes and Perry[3] report the case of an infant, aged 7 weeks, who died suddenly, and was found at the necropsy to exhibit advanced degenerative changes in the coronary arteries.

THE USE OF SURGERY IN PULMONARY TUBERCULOSIS.*

BY

H. MORRISTON DAVIES, M.D., M.CH., F.R.C.S.,

MEDICAL SUPERINTENDENT, VALE OF CLWYD SANATORIUM; CONSULTING SURGEON, UNIVERSITY COLLEGE HOSPITAL, KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION, CHESHIRE JOINT SANATORIUM.

In the treatment of pulmonary tuberculosis, as in that of all other diseases, the simplest methods, carrying the least risk, must be tried first and continued as long as they show a possibility of succeeding. The simplest treatment for many patients with pulmonary tuberculosis is sanatorium treatment, being generally without risk. In a few cases, however, there is the danger that haemorrhage may curtail life before healing takes place under sanatorium regime. Again, sanatorium treatment may be inadequate on account of the acuteness of the disease, weak powers of resistance, recurrence of infection, or because the character of the changes, whether the result of the tubercle bacilli, or of the secondary infection, or of the resulting fibrosis, is such that healing cannot occur without the application of radical additional aid.

In this article it is proposed to consider the problems of how to diminish the relative virulence of the tubercle *bacilli to the resistance of the individual, and of how* to reduce the anxieties and dangers of haemorrhages: how, further, the healing processes and the eradication of the infectivity of the individual can be hastened when the time factor is of importance: and finally, how we can overcome the persistent infections of single large or of multiple small cavities in the parenchyma or in the dilatations of the bronchi.

Where one lung is involved the object is achieved if collapse can be readily secured, but this is not always possible. If the second lung is implicated, the radical treatment of the more seriously affected side may have to be greatly modified, and may even be impracticable

The simplest, but not always the easiest, method of collapse is that of artificial pneumothorax. The purpose here, however, is to discuss those surgical methods which may be accessory or alternative to artificial pneumothorax —namely, hemidiaphragmatic paralysis by phrenic evulsion, thoracoplasty, multiple neurectomy, and extrapleural pneumolysis. If it were always possible to get a perfect collapse with artificial pneumothorax, and if there were no complications to this method of treatment, there would be less need for these other operations. What often indicates the necessity for the operations of thoracoplasty or phrenic evulsion are the failures to obtain complete collapse by artificial pneumothorax, even with the aid of the cautery for dividing adhesions, and the various complications of pneumothorax.

The Operation of Evulsion of the Phrenic Nerve.

This operation consists in exposing the nerve in the neck, dividing it, and then, by traction on the distal end, drawing out the intrathoracic part of the nerve. In a case of complete evulsion the terminal filaments will be torn out from the diaphragm. It is not advisable, however, in certain cases, such as in those in which the nerve is caught up by thickened pleura, to attempt such a complete evulsion: it is satisfactory if some 10 to 12 cm. of the nerve can be removed.

* Contribution to a discussion at the Medical Society of London, February 10th, 1930.

Evulsion of the phrenic nerve has almost entirely superseded simple section, because, by evulsion, it is almost always possible to destroy the connexion of the accessory phrenic with the intrathoracic part of the nerve, and so interrupt this possible additional source of supply to the diaphragm. The operation is performed under local anaesthesia, except in young children. Under ordinary conditions an incision 2 to 3 cm. long is sufficient. Abnormalities of the phrenic nerve are frequent and varied, and it may be necessary to enlarge the incision slightly in order to make certain of finding and distinguishing the nerve which is to be evulsed. At times also, enlarged glands, or the scar tissue of old glandular infections, interfere considerably with the easy exposure of the nerve.

After evulsion, the dome of the diaphragm is paralysed and the muscle fibres gradually atrophy. Three changes occur in consequence. Where the muscle was in a state of tonic spasm, that spasm disappears; when normal or limited respiratory movements were present, they are abolished or may even be replaced by paradoxical movements, the paralysed dome rising as the unaffected dome descends, and vice versa. The third change is the rise of the dome into the thorax, which gradually increases during the ensuing two or three months as the muscle fibres atrophy.

Each of these changes exercises a favourable effect. The paralysis and loss of tone frees the lung, shrunken by the contraction of the pathological fibrous tissue, from the constant strain of the counter-drag of the muscle; while the rise of the dome, and the paradoxical movements when present, allow of a corresponding partial collapse of the lung, which in turn eases, and may even abolish, the drag of the shrunken lung on the mediastinum and its contents. The partial collapse of the lung is not limited to the base; this is strikingly illustrated in some cases by the great diminution in the size of cavities near its apex.

The relief of such symptoms as pain, aching drag, tightness round the base of the lung, and even of irregular tachycardia, when the pericardium is involved by basal adhesions, is among the most immediate results of hemidiaphragmatic paralysis; the presence of such symptoms is therefore an indication for phrenic evulsion. Hemidiaphragmatic paralysis may have a considerable influence also on certain other symptoms, such as cough and sputum. That form of dry recurrent cough due to irritation of the diaphragm is completely abolished. The bringing up of sputum is facilitated, because the expulsive force of the abdominal muscles acts directly on the lung, and is no longer damped by the semi-rigid, tonically contracted muscle.

Very briefly stated, the indications for phrenic evulsion are:

1. In cases of basal tuberculosis. It can be tried also in cases of basal bronchiectasis, but it is only rarely that any real or lasting success is obtained.

2. In cases of chronic basal effusions with thickened pleura: partly to reduce the space, and partly to relieve the dragging sensation.

3. In cases of more generalized tuberculosis when artificial pneumothorax has been tried and has failed.

4. For the relief of symptoms such as pain, dragging, cough, and tachycardia.

5. As an accessory to artificial pneumothorax when the base of the lung is adherent. It is also of particular value in that hemidiaphragmatic paralysis is said to help in preventing the recurrence of them, but I am not convinced that this is so. Phrenic evulsion can be done to check a basal extension in the opposite lung. Hemidiaphragmatic paralysis is said to help in preventing effusions or in checking the recurrence of them, but I am not convinced that this is so. Phrenic evulsion can be done to check a basal extension in the opposite lung. One should always be ready to convert the dome when a lung, long collapsed by thoracic pneumothorax, is being allowed to re-expand, to thoracoplasty. The chief object of the pleural cavity.

6. As a preliminary to thoracoplasty. The chief object as to reduce the size of the lower ribs which require to be resected, to prevent the later [illegible] in a case with an unresolved [illegible]

Thoracoplastic Operations.

The basis of all thoracoplastic operations is the excision of parts of ribs so as to produce collapse of the chest wall by mobilizing these ribs. This has been found to be less drastic than decostalization—that is, the removal of the whole length of the ribs. One essential condition of the operation is that the posterior line of division of each rib should be made at the level of the transverse processes. Another is that the excision of ribs should be carried up to and include the first, since each rib is fixed to the one above by the intercostal muscles and aponeurosis. When this has been done it will be found (1) that the ribs drop downwards, especially at the posterior ends, so that the cut end of the first rib may now lie opposite the transverse process of the third dorsal vertebra, and the others correspondingly; (2) that the lateral cut end of the ribs has become approximated to the spine; (3) that each of the ribs has become tilted downwards (bucket-handle action). These three actions cause the chest wall to fall mesially towards the mediastinum, so that very considerable collapse of the lung is produced.

According to the original paravertebral, extrapleural thoracoplasty as devised by Sauerbruch, the operation entailed division of ribs one to eleven inclusive. It has been realized more and more in recent years that this excessive resection is not always necessary, and that excision of parts of the first eight, seven, or even six ribs may produce a sufficient collapse to lead to the healing of the tuberculous lesion in upper lobe cases. When discussing apicolysis it will be suggested that a thoracoplasty limited to the first four or five ribs only is as efficacious, and is an operation preferable to apicolysis.

The collapse of an extensive thoracoplasty, and more so of a partial one, is not so complete as is the collapse of an uncomplicated pneumothorax, but it has the great advantage of being constant. Provided, therefore, the collapse by thoracoplasty is sufficient to obliterate existing cavities, it can be equally as efficient as the more complete collapse of pneumothorax.

It should be clearly understood that even the most complete thoracoplastic operation produces no crippling deformity. When the patient is clothed it is impossible to know on which side the operation has been performed. There is no drop of the shoulder, nor is there any limitation of the movements of the arms. When stripped the alteration in the angle of the axilla is the main indication from the front; there is flattening behind, and the scapula is bedded-in so that the posterior surface is at the level of the spinous processes.

The indications for thoracoplasty are in the main those for artificial pneumothorax, but the contraindications are much more severe. With one exception a thoracoplasty should not be done until artificial pneumothorax has been tried and has proved valueless.

It is sometimes easy to decide that the amount of gas which it has been possible to get into the pleural cavity is insufficient to be of any value; but occasionally it is very difficult to determine when an artificial pneumothorax which is producing a partial collapse and is exercising a slight control on the symptoms should be given up. In such cases the benefit of the doubt may be given to a more prolonged trial of the pneumothorax in the exudative type of case without cavity formation or much secondary bronchial change. Where there is extensive fibrosis, however, with dilatation of the bronchi and bronchiectatic cavities, it is probably a waste of valuable time to continue with the pneumothorax; this should be abandoned in favour of a thoracoplasty.

Occasionally, when the base is well collapsed by artificial pneumothorax, but not the apex, the basal pneumothorax is supplemented by a thoracoplasty of the upper ribs. When the pneumothorax is done primarily for the control of haemorrhage and is not efficacious, or if a lung, long collapsed, is re-expanding despite pneumothorax of the thorax, then a thoracoplasty is indicated.

A pyothorax complicating a pneumothorax is always a cause for anxiety; if this pyothorax is secondarily infected it becomes a serious menace to life. It may be possible to control the effusion and the pyrexia by an aspiration, but if this fails, a thoracoplasty must be done. The operation should not be too long deferred, since the [illegible]

becoming thickened and rigid, will interfere with the collapse of the chest wall, and the thoracoplastic operation will also be a failure.

There is one type of case for which I consider that thoracoplasty should always be preferred. I refer to those cases of advanced chronic unilateral fibrotic tuberculosis in which there are extensive changes, part cavitation, part great thickening and dilatation of the bronchi and bronchioles. For these cases artificial pneumothorax is only rarely feasible; even where it is, the principal advantage is the building up of the patient's general condition, if necessary, as a preliminary to, and control of the sputum during, the major operation.

The contraindications for thoracoplasty are much more precise than they are for artificial pneumothorax. In the latter the presence of active disease in the other lung is, in itself, no bar; it is rather the anatomical extent of the disease that is the deciding factor. When considering the suitability of a case for thoracoplasty the presence of an active tuberculous lesion in the opposite lung must be regarded as a complete contraindication—with one exception, to be noted directly. It is sometimes difficult, however, to determine whether fine crepitations heard at the apex of the better lung, in which there is a certain amount of fibrosis, are due to active tuberculous disease or to a catarrhal condition. If these signs have been watched over a period of some months and show little variation in area or quality, and the indications in the more seriously diseased lung are very strong, and if, further, after a preliminary phrenic evulsion these crepitations are not deleteriously altered, then a thoracoplasty need not be considered as contraindicated.

The single exception referred to above is in the case of haemorrhage. Bleeding from the more damaged lung, when it is periodically recurring and is of sufficient quantity to endanger the patient's life, and when the fear of it has become an ever-present terror, justifies certain additional risks. In such cases it is permissible, in my opinion, to attempt to control the bleeding by thoracoplasty, when no other means have been found practicable, even if there is a small area of activity in the less involved lung.

Tuberculous enteritis seems to me to be an absolute contraindication. Cachexia, a failing heart, albuminuria, unless transitory, and diabetes unless well controlled, are also contraindications. Tuberculosis of the larynx is not necessarily a bar unless there is considerable oedema interfering with the airway, or involvement of the epiglottis interfering with nutrition.

Multiple intercostal neurectomy has been tried by J. Alexander in certain cases in which there are contraindications to thoracoplasty. The nerves are resected under local anaesthesia. Slight collapse of the chest wall and immobility are obtained. There has been apparent benefit in some cases, but the number so treated is too small as yet for any definite conclusions to be drawn.

Extrapleural pneumolysis is the local collapse of the lung, which is secured by separating the parietal pleural membrane from the chest wall and by filling the space thus formed with a foreign body to prevent its return. This operation, which may be performed as an independent one, is generally used to induce collapse of the apex of the lung, and it is then called apicolysis. It is often supplemented by hemidiaphragmatic paralysis, and may be used to increase the collapse obtained by a thoracoplasty, especially in cases with thick-walled upper lobe cavities.

Various substances have been employed to fill the cavity between the parietal pleura and the chest wall, so that the collapse of the underlying lung may be maintained. Paraffin, however, may produce an extrapleural effusion, which, finding its way through the divided tissues, escapes and carries the paraffin with it. Fat and fatty tumours may degenerate and form an abscess. I have found a pedunculated graft of the pectoralis major in men, or the breast in woman, the most satisfactory.

As already mentioned, however, when an apical collapse is needed, a very extensive resection of the upper four or five ribs gives a more certain and satisfactory result.

It has been possible to touch the fringe only of the subject in this article. No reference has been made to technique or to the rarer operations.

EFFECTS OF AIR IN THE VASCULAR SYSTEM AND THE MECHANISM OF DEATH.*

BY

D. T. BARRY, M.D., D.Sc., F.R.C.S.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF CORK.

THOUGH some surgeons profess to entertain no fears concerning the evil results of the introduction of air into a vein, most operators believe that such an accident is one to be carefully avoided. Experimental work on the subject was pretty extensive before modern apparatus like the electro-cardiograph could be used for interpretation, but not in recent times. The conclusions arrived at by experiment, though presenting general agreement with regard to salient effects, show certain discrepancies. The literature on the subject is not very extensive. Laborde and Muron[1] injected large quantities of air (500 c.cm. and more) into the jugular vein of the dog at a slow rate without fatal results, whereas rapid introduction of 100 to 200 c.cm. caused paralysis of the heart by distension. Couty[2] described most of the symptoms observed in the present experiments. The lack of an electro-cardiograph in his and other researches did not permit correct observation and interpretation of the cardiac phenomena. Begouin[3] allowed air into the jugular vein in cats and dogs; he also blew it into the vein by the mouth. Withdrawal of air from the ventricle by means of an aspirator was practised with apparent benefit. Depage[4] says that the entrance of air into veins is not so dangerous as is generally believed. He cites two cases of its occurrence during operation which were cured by artificial respiration, and quotes instances from the work of other surgeons. The three main theories of the mechanism of death—the nervous theory (Morgagni, Bichat), the pulmonary theory (Poisseule, Bernard, et al.), and the cardiac theory (Magendie, Amussat, et al.)—are discussed. Jung and Auger, in a fairly recent paper,[5] sum up the general views concerning the mechanism of death, the chief factors being rapid fall of arterial pressure, the entrance of air into the coronary vessels, and ventricular fibrillation. There is no reference to any influence of the respiratory mechanism, except in so far as disturbance of function may be implied as a result of the fall of blood pressure, and in no work up to the present account apparently is there a reference to the use of the electro-cardiograph. Little evidence is provided by the experiments done by myself to favour the view that ventricular fibrillation is a common cause of death after injection of air. The results of these experiments on dogs weighing 10 to 15 kilos are here considered in two chief categories.

A. Thorax Closed.

If 50 c.cm. of air or more be pretty rapidly admitted into the jugular or saphenous vein of a dog with closed thorax and natural respiration a fairly definite train of symptoms is produced—namely, respiratory distress, muscular agitation, polypnoea, marked fall of arterial pressure, and irregular action of the heart. The heart sounds are sometimes audible at a distance from the animal, and have a gurgling character. The electro-cardiogram may exhibit arrhythmia, extrasystoles, inversion of the T wave, etc. A dog thus treated does not necessarily die as a result, in fact, it usually recovers quite fully in the course of twelve to twenty-four hours. If a second large quantity of air be introduced before the effects of the first have passed off the animal may succumb to its influence, and death is generally preceded by a period of apnoea.

In deep anaesthesia the symptoms may be somewhat different from the above. Especially in the case of two dogs under chloralose, there was no marked polypnoea, and apnoea set in early, the effects of one injection being fatal. These two experiments were performed at the Institut Marey, in conjunction with Mr. L. Bull, to whom I am greatly indebted for help and counsel in the taking and interpretation of electro-cardiograms.

The most constant symptom, observed in practically all cases, and varying in degree with the amount of air admitted, is the fall of arterial pressure. When large

* Received for publication January 17th, 1930.

quantities of air are introduced into the venous circulation the sudden drop in arterial pressure is due to mechanical obstruction to the venous flow through the pulmonary artery. The obstruction is soon overcome by an immediate process of breaking up of the air into small particles, so that the frothy blood passes to the lungs. It is remarkable how the pulmonary artery rapidly becomes free; post mortem it shows but few particles of air in the lumen either of the trunk or of the large branches. These appearances give little support to the view that the pulmonary factor is of importance in the mechanism of death.

Does anaemia of the bulbar centres account for the polypnoea? Not fully; polypnoea is sometimes developed when small amounts of air are introduced into the veins which are not sufficient, either in amount or in rate of entrance, to cause an appreciable lowering of arterial pressure. A reflex factor in the causation of the polypnoea is not unlikely, the afferent impulses arising within the cardiac area or in the carotid sinus, which, as shown by the work of Hering,[5] Heymans,[6] and others, is the seat of important reflex control of the vascular system in general, and of the encephalic blood pressure in particular.

In a paper on this subject read at a meeting of the Société de Biologie in Paris[1] I drew attention to apnoea as a prominent feature in the effects of injection of air. It is maintained in some cases for quite long periods before cardiac death. The respiratory centre fails, and the anomalous condition is seen of a heart beating, however slowly and irregularly, with no air entering or leaving the lungs, and a very low arterial pressure. The role of apnoea in the mechanism of death seems to be an important consideration, though it has not been given prominence as a factor in this. When sufficient air is injected to cause death apnoea is usually seen before the end, but it needs a larger amount of air to cause it than in deep anaesthesia. In animals with cut vagi the symptoms were like those of deep narcosis with intact vagi. Probably the vagus is an afferent path, not necessarily the only one, for the impulses to the respiratory centre, a path which is deleteriously affected in deep chloralose anaesthesia. In this condition and in vagotomized animals the polypnoeic disturbance is much less than in other cases, and the polypnoea is to be regarded as a mode of defence of the organism. Apnoea of short duration does not necessarily portend a fatal result. But if the apnoeic phase lasts more than half a minute or so it is a certain sign of failure of further resistance, and indicates a fatal termination.

B. *Open Thorax.*

When the chest is opened and artificial respiration performed the symptoms caused by the introduction of 50 to 100 c.cm. of air into the jugular vein are different from those mentioned in the case of natural respiration. The blood pressure falls as before, but of course there is no evidence of interference with the respiratory mechanism and no indication of the reactions of the respiratory centre in response to reflex or other influence. The heart is the organ which succumbs, and fibrillation is common in these conditions. In case of closed thorax the nervous centres die for lack of blood, consequent on the mechanical obstruction of the circulation, while the heart remains active for a time and is apparently capable of recovery if conditions can be made favourable. The duration of the period of starvation of the centres by deprivation of blood is a factor in causing the death of the centres. In some cases this period is fairly short.

How does the heart maintain its activity without an efficient coronary circulation and in conditions where one would expect serious anoxaemia? Probably a small supply of oxygen is sufficient to keep up the discharge of impulses from the sino-auricular node, and this supply may be available for a time by direct diffusion of oxygen from the arterial blood in the right auricle, which remains bright red for a long time. Removal of the products of combustion in the absence of a proper venous circulation may be also effected by diffusion, aided by contraction of [illegible] tion of [illegible] this fact, hydration should no

Conclusions.

Dogs can recover from the effects of introducing about 100 c.cm. of air into the jugular vein.

Resistance to the effects is diminished in deep anaesthesia and after section of the vagi.

The heart in some conditions is the organ which fails in fatal cases, but failure of the respiratory centre is the cause of death in others. Apnoea is an important symptom indicating the loss of reaction in this centre. Ventricular fibrillation is not a common cause of death.

With regard to treatment, the inhalation of oxygen while the respiratory centre is active is indicated. Artificial respiration should be tried when it shows signs of failure. As for bleeding and aspiration, they inspire little faith. Animals in experiment exhibit marked powers of natural recovery, and one is very prone to attribute to some remedial measure an undue beneficial effect.

THE TREATMENT OF DESPERATE CASES OF DIABETIC COMA.

BY

R. D. LAWRENCE, M.D., M.R.C.P.,*

CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL.

MANY physicians must have had the disappointing experience of losing a certain proportion of cases of diabetic coma even since the introduction of insulin. From all countries records and statistics show a varying number of patients who die in spite of energetic treatment with insulin. Such has been my experience. It therefore seems worth emphasizing an aspect of the treatment by means of which recovery has followed in two desperate cases of coma—in-patients who I am sure would have died under my treatment of a year ago. The deciding factor in their recovery was, in my opinion, the administration of *extremely large* quantities of intravenous fluid, hypertonic saline and gum acacia solution.

The most dangerous cases of coma requiring such treatment are easily differentiated by one or two simple clinical observations from the less severe cases which respond readily to adequate doses of insulin alone. Typical air hunger and varying degrees of unconsciousness are present in both types, and chemical tests show a large excess of sugar and ketone bodies in the urine and blood. In addition the desperate cases show evidence of dehydration, collapse, and circulatory failure. The pulse is rapid and feeble, the blood pressure very low, the veins are empty, the tissues drained of water, and the most striking sign is the *low eye tension*. This may be so extreme and the eyeball so flat that one has almost to lift the lid to make sure the eye has not previously been removed. There is a real "melting of the flesh into water" on old description of diabetes—or, more exactly, a melting away of water from the flesh, dehydration. This *dehydration* is produced by the intense polyuria of the preceding days and the failure to absorb fluid because of vomiting and unconsciousness. The volume of the blood is reduced, the blood is concentrated, of which a raised haematocrit content is evidence.

Another feature of these desperate cases is a very [illegible] secretion of urine, sometimes actual anuria. It has been suggested that kidney failure is the cause of death in such cases, and that death is really a uraemic one. In my opinion, however, oliguria or anuria is due to dehydration and a low blood pressure. An exactly [illegible]

[illegible] taking on insulin for the Medical Research Council

* [illegible]

condition is found in cholera—dehydration, collapse, and anuria. Certainly in all the cases of diabetic coma I have seen proteinuria, casts, and often blood cells have been found, but these have disappeared in a few days after recovery, and the oliguria within twelve to thirty-six hours after the re-establishment of the body fluid and circulation. This condition is accompanied by nitrogen accumulation in the blood and blood urea concentrations of 80 to 100 mg. per 100 c.cm. or even higher, due essentially to the dehydration. At the same time the blood chlorides are very much depleted, as in cholera.

The chemical findings in the blood in diabetic coma may be usefully divided into two groups, which may be called (1) the diabetic, and (2) the dehydration complex, all the features of the second being present also in cholera.

1. *Diabetic Complex.*
   - Hyperglycaemia.
   - Excess of ketone bodies.
   - Low alkali reserve.
2. *Dehydration Complex.*
   - Tissue depletion of water—for example, low eye tension.
   - Low blood volume and pressure.
   - Concentrated blood, high haemoglobin and specific gravity.
   - Nitrogen retention—high blood urea.
   - Low blood chlorides.

The first derangement is rectified by insulin, the second by abundance of fluid, which in desperate cases should be given in *large quantities* and preferably *intravenously*. The importance of the administration of fluid to coma cases has been known for years, and was recently brought out at a discussion at the Royal Society of Medicine; but the quantity of fluid necessary has not been emphasized or defined.

The following three cases are recorded, the first fatal, to illustrate the procedure and the amount of fluid that may be necessary in dealing with such cases. All were completely unconscious, and only such details are given as bear directly on the treatment.

CASE I.

Male, aged 52. Seen at noon: pulse 130 feeble, temperature 97° F.; very low eye tension. Urine: sugar ++++, ketones, Fe_2Cl_6+, blood sugar 1.531 per cent., alkali reserve 13 per cent. Insulin 40 units was administered intravenously, and 60 units subcutaneously. *Between 1 and 2.30 p.m. 2 pints of normal saline* were given subcutaneously and 1½ pints by the rectum, all completely absorbed. As this seemed a large amount I unfortunately did not give intravenous fluid. At 2.30 p.m. 3 ounces of urine were obtained, containing less ketone bodies: albumin, trace; casts, granular. At 3.30 p.m. the blood sugar was 1.30 per cent., the pulse 132 and slightly fuller, and 100 units were given. At 6.30 p.m. a few cubic centimetres of urine were collected, loaded with sugar, but with much less acetone—a negative FeCl. Blood sugar 1.020 per cent., temperature 102° F. Shortly after, the pulse collapsed almost entirely, but the patient was partially revived by adrenaline, 3 minims intravenously. Camphor and ether was administered, and a pint of hypertonic saline was being given to the moribund man when he died. No post-mortem examination was obtained. (It is interesting to note that the blood urea was 153 mg. per cent., and the chlorides (whole blood) 290 mg. per 100 c.cm.—extremely low. The increase in the osmotic pressure of the blood produced by the extreme hyperglycaemia (1.53 per cent.) was balanced by an exactly corresponding diminution of the sodium chloride.)

Total fluid: 2 pints subcutaneously, 1½ rectally = 3½ pints = 2 litres.

CASE II

Female, aged 53; admitted to King's College Hospital at 3.30 a.m. Temperature 97° F., pulse 86 and very feeble; intense dehydration; eyeball hardly palpable. Urine: sugar +++, acetone FeCl ++, albumin +, casts granular and blood. Blood sugar 0.600 per cent. She was given 120 units of insulin and 2 litres (3½ pints) of hypertonic saline from 4.30 to 5.30 a.m., and strophanthin 1/250 grain. 6.30 a.m.: Temperature 97.4°, pulse 112 and feeble. 10.30 a.m.: Urine (only a few cubic centimetres by catheter), sugar +++, FeCl +. Blood sugar 0.520 per cent. Insulin 100 units intravenously. From 11 a.m. to 3 p.m. 3½ pints of normal saline subcutaneously. 4 p.m.: Urine (a few c.cm.), sugar +++, FeCl 0, Rothera +: blood sugar 0.328 per cent. Dehydration obviously less; eye tension higher; temperature 98.7° F., pulse 124, still very feeble. She was given 1 pint of gum acacia *plus* 6 ounces bicarbonate solution (20 grams), and adrenaline 6 minims intravenously, which caused an immediate improvement of pulse and colour. Insulin 20 units and glucose 20 grams by mouth were now given four-hourly. At 10.30 p.m. the pulse (120) became less full, and 1 2 pint of gum acacia with 1½ pint (200 c.cm.) of 5 per cent. glucose, 20 units of insulin, and 4 minims of adrenaline were given intravenously. After this the pulse remained satisfactory, the eye tension was practically normal, and consciousness was partially recovered during the night. (It is interesting to note that the plantar reflex was extensor during unconsciousness, but became flexor next day.)

Total fluid: 9 pints 6 oz. (5.5 litres); 7 pints (4 litres) intravenously in ten hours.

CASE III.

Female, aged 54. Admitted 9.30 a.m. Very dehydrated, moderately low eye tension, pulse hardly felt, air hunger giving way to *feeble, intermittent gasps*: Urine: sugar ++++, FeCl ++++, albumin +, and granular casts. Intravenous injection started immediately, and from 9.30 to 11 a.m. 2.5 litres (4 pints) of hypertonic saline and finally 1 pint of gum acacia solution were given, the first litre containing 100 units of insulin, 5 minims of adrenaline, and 20 grams of sodium bicarbonate (5 drachms). At the end of this the pulse had considerably recovered, and the blood sugar was 0.356 per cent. No blood could be obtained before the injections on account of her desperate condition. From 11 a.m. to 1 p.m. she received 2 pints of normal saline subcutaneously, containing 30 grams of glucose, and by 2 p.m. the pulse was satisfactory (rate 115) and the eye tension higher. A small quantity of urine was obtained by catheter at 1 p.m., and the secretion was well established by 7 p.m. She became conscious enough to swallow, and was given 20 units of insulin and 20 grams of glucose four-hourly by the mouth with abundance of fluid.

Total fluid 7 pints (4 litres) in four hours, 5 pints intravenously in 1½ hours.

DISCUSSION.

It will be noticed that in Case I the patient, who died, *received only 3½ pints of fluid and none intravenously until* he was almost moribund. The other two patients, who recovered, received much more fluid, largely intravenous, at the beginning of treatment. One required 9¼ pints, the other 7 pints before the circulation seemed satisfactory. There is no proof that the first patient would have recovered with more intravenous fluid, or that the others would have died with less; but this is my strong impression, and I certainly the circulatory condition of the first (fatal) patient was better when first seen than that of the others.

The following points in the treatment merit a fuller discussion.

Technique of Injection.

The intravenous injections were given in all cases with a *Jubé blood transfusion syringe*. This is by far the simplest and most easily controlled method. Quite a small needle (size 12–14) can be used, and it has not been necessary to cut down on a vein, although they have all been collapsed. A small piece of rubber tubing (boiled) leads from the syringe and dips into the jug containing the infusion. It is my practice to add insulin, adrenaline, or any other stimulant (caffeine or digitaline, etc.) to the fluid in the jug. Also it is not easy with a small Jubé syringe to introduce the fluid too fast, and yet, as it can be injected under pressure, there is no risk of blockage or failure as with gravitation methods. The pressure and rate of injection are under perfect control. The fluid has been given at the rate of a litre in half to three-quarters of an hour, never faster. Such a syringe is invaluable, and can be used for aspirating as well as injecting fluids.

Nature of Intravenous Injections.

Double-strength physiological saline (1.8 per cent. sodium chloride) has been used for the first infusion in these and other less desperate cases. This strength was chosen arbitrarily in a hurry, because I did not know what strength of hypertonic saline was usually given. I subsequently found that 1.2 per cent. saline is given in the treatment of cholera (Rogers), and perhaps this would be better. Hypertonic saline was given because the available evidence shows that the body is depleted of sodium chloride and the blood chlorides are low (see Case i). It is an open question whether hypertonic has any practical advantage over isotonic saline (0.9 per cent.), but it is theoretically preferable. Gum acacia solution (7 per cent.) has been given after the saline because it is a fluid which remains in the vessels. I believe that much of the saline rapidly leaves the blood and goes to the dehydrated tissues, which can be observed to fill up during an infusion. It has been clearly noted in these cases that the effect of the pint of gum solution has been to amplify and fill the pulse more than the preceding larger volume of saline.

Volume of Fluid.

This paper advises the administration of very large quantities of intravenous fluid, much larger than has been advocated elsewhere, except in the treatment of cholera. In neither case, nor in other less severe cases, has there been any untoward sign of cardiac embarrassment or dilatation, or of general or pulmonary oedema, although the tissues visibly filled out during the infusions. The absence of such signs may seem remarkable in Case ii, where 9¼ pints (7 intravenously) were given in eighteen hours and only a few ounces of urine were secreted in twenty-four hours. The dehydrated tissues must be able to absorb such quantities without any surfeit of fluid. It is impossible to state dogmatically the ideal amount of fluid to give, as this must vary in every case with the body weight and degree of dehydration. The following theoretical considerations may be of interest.

If we knew the weight of the patient a few days previously and were able to weigh the patient when first seen in coma, some idea of the water loss could be obtained. This was impossible in the above cases. But recently another patient, not completely unconscious, was weighed on admission to hospital and again twenty-four hours later after treatment with insulin and fluid. The patient gained 12 lb. in weight without any oedema—a gain in weight which did not fall on succeeding days. In that twenty-four hours she received only 3 pints intravenously, but abundance of fluids (not measured) by mouth, and only 60 grams of carbohydrate as food. This 12 lb. is equal to 16 per cent. of her body weight, and is about 10 pints of water. It may be taken as her amount of fluid loss, and she was not by any means an extreme case of dehydration, as the eye tension was only slightly reduced. In some cases the percentage loss of water and the total loss must be much greater. When we consider that the body of a man of average weight contains over 40 litres of water, there is no doubt that over 4 litres, and probably 6 or 8 o. more, must be lost in extreme dehydration (7 to 14 pints). It is not surprising, therefore, that in Case ii, the most extreme, the patient showed no evidence of excessive administration of fluid when 9¼ pints had been given. Judging from the relatively poor condition of the pulse after 7 pints had been given, and its immediate improvement after only one pint of gum (the eighth), it seems probable that most of the intravenous fluid leaves the circulation for the tissues.

It is interesting to note the quantity of intravenous hypertonic saline given in the treatment of cholera. Rogers advocates 3 to 6 pints of 1.2 per cent. saline given at the rate of 4 oz. a minute—that is, 1 pint in five minutes (I have never given it so quickly in diabetic coma). Cox of Shanghai advises continuous intravenous isotonic saline for *several* hours, until collapse is overcome, at the rate of 2 oz. per minute. That is, 1 pint in ten minutes or 6 pints in the first hour—very comparable to the amounts I have given, but far exceeding my dosage when carried on for several hours. The conditions, however, are different, for the loss of fluid will continue in cholera while the diarrhoea lasts, whereas the loss in diabetes gives way to oliguria or anuria.

From the practical point of view, we may be guided by the following clinical considerations. Enough intravenous saline should be given as soon as possible to fill visibly the shrunken tissues and re-establish the fullness and strength of the pulse. This may require 3 to 5 or more pints of fluid, and I consider it wise to finish the infusion with a pint of gum acacia, a fluid which remains in the circulation while much of the saline rapidly leaves the blood and enters the tissues. It is desirable on theoretical grounds to commence with hypertonic saline (1.2 to 1.8 per cent.), but I have no proof that this makes any practical difference. After the intravenous treatment, it would seem advisable to give continuous subcutaneous for rectal saline, unless this is certainly localized and is not being absorbed into the general circulation, an indication of the body is sufficiently supplied with fluid. If the pulse volume collapses, more intravenous saline and gum solution (1 2 to 1 pint) should be given.

The complete recovery of the eye tension is a sign that sufficient fluid has been given, but it is noticeable that the eye tension (and the secretion of urine) is slow of recovery, even when dehydration of the rest of the tissues has been overcome. A series of estimations of the haemoglobin percentage of the blood might indicate when sufficient fluid had been given, but is open to fallacies. The heart should be watched for signs of dilatation, and the ankles and lungs for oedema. I have not observed such danger signals occur, and think the risk is extremely small. In any case this risk must be taken if these moribund patients are to have any chance of recovery.

It may be that the ketone poisons *per se* are an important factor in producing the circulatory collapse, but there is no proof of this. I have, at any rate, observed several fatal cases in past years in which the ketonuria and ketonaemia has been greatly reduced by insulin without recovery of the circulation; these patients died. in my opinion, because I failed to supply the necessary large quantities of fluid.

I do not propose here to discuss the dosage of insulin, the necessity of warmth, and treatment with cardiac stimulants, although I think it important in every collapsed case to give a few minims of adrenaline in the first infusion. This has a remarkable, if temporary, effect in stimulating the circulation. Nor shall I discuss the advisability of giving sodium bicarbonate to replace the depleted alkali reserve and abolish acidosis. It may be noted, however, in the latter respect, that the hypertonic saline can very quickly remove the main symptoms of acidosis—the air hunger. In the last patient I treated, a litre of hypertonic saline completely abolished the air hunger in half an hour, before the infusion was finished or the pulse had recovered satisfactorily.

SUMMARY.

Attention is drawn to dehydration as the immediate cause of death from circulatory failure of desperate cases of diabetic coma. They die, as do cholera patients, from depletion of tissue and blood fluids, and often in the anuric state. The condition is recognized clinically by a feeble, empty pulse, shrunken tissues, low eye tension, and oliguria or anuria. In addition to insulin they require immediately large quantities of fluid, preferably intravenous. A treatment with hypertonic saline and gum acacia solution is described.

MEDICAL, SURGICAL, OBSTETRICAL.

BILIARY CIRRHOSIS IN AN ELDERLY WOMAN

BILIARY cirrhosis of the liver is said to be common in young adults of the male sex. The following case, therefore, occurring in an elderly woman, appears to be worthy of record.

About 11.30 a.m. on January 19th I was called to see Mrs. X., aged 67, who complained of severe pain in the pit of the stomach. The onset was sudden, six hours previously, when she vomited on one occasion, some bile-stained fluid. She was pale and collapsed but not markedly emaciated. She looked ill, toxic, and exhausted with cold clammy skin, submormal temperature, and rapid pulse. the tongue was dry and covered with a brown fur. There was repeated retching, with gaseous eructations. The abdomen was flaccid and not distended; there was epigastric tenderness. The liver was slightly enlarged, and on percussion the lower border was found to be one fingerbreadth below the right costal margin. No other abnormality was found in the abdomen or chest, apart from an occasional rale at the base of the left lung. No examination-stools were available for examination.

From 11 p.m. (her relatives stated) until 5 a.m. the following morning she repeatedly vomited black, tarry material, about a pint in all, and died suddenly at 7 a.m.

Previously, she had had rheumatic fever in childhood, and during the last few years, frequent attacks of bronchitis. She had had attacks of diarrhoea, off and on, for the last two or three years, and had suffered from this continuously for the last three months. She always had a yellowish complexion, but had been of normal temperature in her habits.

At the necropsy all the abdominal concavity, parietal and visceral, stomach and greater omentum, were tinged with bile [illegible]

was about one pint of foul-smelling brown fluid in the peritoneal cavity. The mucosa of the lower end of the œsophagus and of the stomach, duodenum, and upper two-thirds of the ileum was congested. Small varicose veins were visible at the lower end of the œsophagus, but none was seen to have been ruptured. Apart from catarrhal exudate covering the mucosa, the stomach was empty. The catarrhal changes were most intense in the duodenum and upper part of the ileum, where the bowel was plum-coloured and distended, and the mucosa was brick-red in colour and covered with coffee-coloured exudate; these appearances faded away towards the lower end of the ileum. The large bowel contained solid faeces throughout. No possible cause of intestinal obstruction was found.

The liver was slightly and uniformly enlarged; the surface was smooth and of greenish-yellow colour, with small congested areas; the organ was friable, the cut surface was uniformly yellow and of granular appearance, being divided into innumerable small islands by minute congested areas; no gall-stones were found in the gall-bladder or bile ducts. The spleen was slightly enlarged, firm, and congested. All the other viscera appeared normal, except the lungs, which showed some hypostasis at both bases. There was about half a pint of brownish-red fluid in each pleural sac.

The diagnosis was confirmed microscopically. A section of the liver showed that, although the lobular structure of the organ was recognizable, necrotic areas in which the liver cells were destroyed and separated from each other were numerous. A moderate amount of small, round-celled infiltration was seen in the portal areas, de-quamation of epithelium had occurred in the bile ducts, but there was little evidence of fibroblastic reaction or of new formation of bile ducts.

STRANGULATED HERNIA IN AN INFANT.

I was recently called in to see a case of strangulated inguinal hernia of the right side in a male infant 5 weeks old. The clinical details are as follows.

On the previous evening the mother noticed a lump in the right groin about the size of a small egg, which appeared as the baby was crying. The infant refused food at 5 a.m. next day, was sick about 10.30, and had only passed a little blood from the rectum. It had not been particularly strong since birth. On examination a fairly freely movable swelling was apparent in the right inguinal region. This swelling was translucent, and it was by no means certain whether we were dealing with a hernia or a cyst. The fact that a neck could just be felt, which appeared to pass up into the abdomen, and the history, led us to advise operation.

At the operation a cystic swelling presented, with the testicle lying behind it; when this was opened it was found to contain a quantity of clear fluid, and at the upper end a knuckle of large gut. The neck of the sac had to be enlarged before it was possible to reduce the hernia. The infant is doing well.

I think that the extreme youth of the patient warrants the case being put on record.

DEATH DURING SPINOCAIN ANAESTHESIA.

HAVING read articles lately on the subject of spinocain anaesthesia for abdominal operations, I think that the following case may prove to be of interest.

A man, aged 58, suffering from carcinoma of the caecum, was operated on some ten days ago, spinocain being injected at about the level of the eighth dorsal vertebra. The anaesthesia was supplemented with gas and oxygen. All went well for an hour and ten minutes, when the heart ceased beating and the respiration entirely stopped. With massage of the heart through the abdominal wound and intracardiac injection of adrenaline the heart resumed its function, after fifteen minutes, during which time not a single beat had been felt. Oxygen was administered through a laryngotomy tube; the operation was proceeded with and completed. The heart continued beating for three and a half hours after it had resumed its function; oxygen being administered, with CO_2, and artificial respiration being kept up with relays of assistants until death.

A remarkable feature was that rigor mortis had set in in the neck fully two hours before the heart finally stopped. The spinocain had been injected with the patient lying on his left side, the operating table being level; after the injection the patient's head was lowered, and kept in that position during the progress of the operation.

Reports of Societies.

AMPUTATIONS AND THEIR RELATION TO THE ARTIFICIAL LIMB.

AT a meeting of the Section of Surgery of the Royal Society of Medicine, on April 2nd SIR HOLBERT WARING presiding, a discussion was held on amputations and their relation to the artificial limb.

Mr. C. MAX PAGE, in opening, said that the surgery of amputations, although it represented the oldest branch of the subject, remained somewhat academical in its teaching until the war. The large number of amputations which then took place in this and other belligerent countries produced new ideas and methods. The early conclusions which traversed pre-war teaching had been made clear by Mr. Muirhead Little, who had produced a most valuable book of reference on the subject. Experience of the last ten years had further crystallized views on certain practical points, and the speaker's role in that discussion was to indicate the attitude of the operating surgeon to the problem. The general principles which governed the technique of any final amputation in either extremity might be defined as those which gave the stump the following characters: (1) approximately conical shape, except when the amputation was very close to the trunk; (2) ability to provide a lever of sufficient length for the attachment of an artificial limb suited to the level of the amputation; (3) closely covered by healthy, well-nourished skin or scar, both of which should be mobile on the deeper structures; (4) with no part tender on pressure or abnormally sensitive. For the below-knee amputation everyone was agreed that the ideal length of tibia to leave, circumstances permitting, was 7 inches, but a stump with as little as 4 inches of tibia was quite capable of controlling an artificial limb. If more than 7 inches of tibia was left it would be covered by skin of poor nutrition, which would almost inevitably break down and cause inadequacy of support for prosthesis. In leaving 4 or 5 inches of tibia it was worth while to remove the fibula entirely, thus diminishing the risk of pressure sores. In above-knee amputations the length which appeared to give the most satisfactory functional stump was one containing 10 to 12 inches of femur. One was tempted to spare as much of the femur as possible, but a rather long thigh stump often proved unsatisfactory. He was interested to see that in America and Germany the Stoke–Gritti amputation, which left something like 14 inches of femur, was very popular. It aimed at producing an end-bearing stump, but in the experience of limb-fitting centres in England these end-bearing stumps in the thigh had proved a failure.

The speaker then passed to some points in technique in an individual amputation which might affect the individual stump. The flaps should be approximately circular in shape in order to interfere with nutrition as little as possible; their total length should be little greater than the diameter of the limb at the level of section, and they should be of skin only. It was of interest to note that many American surgeons advocated the suture of muscle or tendon at the end of the bone or across it. The reason the flap approached to a circular or elliptical shape the better the nutrition was maintained. With regard to the inclusion of muscle in the flaps, the importance lay in cutting a wedge of muscle at the base of the flap in order to maintain nutrition, and not for any other purpose. In the treatment of bone, to avoid spur formation his own practice was to divide the periosteum about half an inch above the level of the saw cut, so that this passed through bone and not through periosteum at all. Attempts to cover the end of the bone with a graft in his experience led to failure and necessitated a re-amputation. He held the strong opinion that osteoplastic treatment of the cut end of the bone was not desirable. In the treatment of the nerves at the end of the stump it had been customary to identify as many of the large nerves as possible, pull them down, crush them, ligature them, and cut them off. The rather gross handling of large nerve trunks was overdone, and many of the patients had post-operative pain, which might be the basis of permanent subjective pain. The nerves

should be isolated for a distance of about 1 inch from the line of muscle section, crushed and ligatured, and the stump injected with absolute alcohol; this would at any rate ensure painless convalescence. The formation of nerve bulbs was inevitable; the only question was how far they could be got out of the way of pressure. They clearly should not be attached to the scar, and at the same time they must not be allowed to form at such a level that they were pressed upon by the artificial limb. With regard to drainage, he had always practised this with an amputation stump of any size.

Mr. P. JENNER VERRALL endorsed a remark made incidentally by Mr. Max Page in condemnation of the Syme stump. He had come across it first in the East, and it was an admirable amputation for the native who had no possibility of wearing an artificial limb; but in Europe, and especially in this country, where artificial-limb fitting had reached a high development, the Syme after six or seven years tended to go wrong. In the above-knee amputation he used an anterior flap and a very short posterior flap. The importance of spurs, he thought, was greatly exaggerated. His custom was not to treat the periosteum in any exceptional way; he divided it straight on the level of the bone. Spurs were unimportant except when they happened to be situated directly underneath the scar. He had used drainage for years at Roehampton and other places, but during the past year he had given up; if he was in any doubt he stitched loosely with interrupted stitches. Splinting of the knee for below-knee amputations was very important. A large haematoma did occasionally occur, and then it was necessary to evacuate; the cases in which a haematoma was very likely were those in which, on the operating table, when the tourniquet was taken off, one made the remark, "I cannot see why this will not bleed." Three weeks in bed was always very important in amputations. In treating nerve ends, the speaker certainly did not pull them down to any large extent, and he agreed that the minimum of trauma was very desirable. He condemned the use of plaster pylons below the knee. In their favour was the fact that the patient obtained an orientation of his walk early, also that a plaster pylon would save money because there would be less limb-fitting afterwards; but against this the patient had an unnatural gait, and, what was more important, he had never seen a below-knee amputation treated in this way which did not rub sores. The first cause for unsatisfactory stumps was to be traced to the circulation. The nerves most likely to be troublesome after amputation were the cutaneous ones; it was not the deep nerves that gave trouble. Sebaceous adenomata up the inside of the thigh were a great trouble; if it was necessary to deal with them surgically extensive resection of the skin should be performed, removing the whole area, but the use of white precipitate ointment would avoid much trouble. In a final word on arm amputations, the speaker said that having dealt with the median and ulnar nerves in the forearm, there sometimes ensued tender ends of the radius and ulna. A good practice was to strip back the periosteum and dig out the medulla, smoothing down the ends of the bones with a file and making them as neat as possible.

Dr. R. D. LANGDALE-KELHAM said that during the war most of the belligerent Governments arranged for the training of a certain number of medical men in artificial-limb fitting. Limb-making in the early days was a more or less empirical business, and the fitting was done on the principles of trial and error, but now a more exact science had developed. The civil population, however, being denied the result of such experience as had been obtained at Roehampton, was still to a great extent in the hands of the limb-makers, who varied very greatly in their anatomical knowledge, some being good and others indifferent. In 75 per cent. of the cases in which distress and discomfort were experienced the reason was the fitting of an unsuitable limb. The speaker discussed and demonstrated the different types of limbs available, including two main types for good above-knee stumps, one known as the American type, with central knee control, and the other depending on a special type of pelvic band and special knee construction. The purpose of the pelvic band was to suspend the limb, to control it, and to support it. In all types of good above-knee limbs the socket was so moulded around the stump that the patient felt that the artificial limb was part of him. It was always advisable to under-support rather than over-support the patient. By under-supporting him one encouraged him to apply his own powers. His experience of a very large number of cases at Roehampton was that the average thigh stump which required a rigid pelvic band had a length of 7 inches from the tip of the trochanter. Long stumps, over 12 inches, would give rise to circulatory troubles sooner or later, leading to re-amputation. The Stokes-Gritti amputation was still popular, but he did not like it, and he shared the dislike of the previous speakers for the Syme, especially from the point of view of the futuro of the patient. About ten years seemed to be the average length of a Syme amputation. There were certain surgical objections to the Syme; callosities formed sooner or later, and became painful. They occurred chiefly in two places, parallel to and running just beneath the anterior scar, and also on the bearing surface itself. The ideal site for the below-knee amputation was 6 to 7 inches below the knee. In conclusion, he pleaded for closer co-operation with limb-makers. The better the limb-maker the more he welcomed surgical co-operation. He also mentioned the indebtedness which limb-fitting surgeons felt to a number of pioneers, notably Mr. Muirhead Little and the late Mr. Openshaw.

Captain A. R. MAXWELL addressed himself to amputations of the upper extremity. At least three factors had to be considered—the surgical, the technical or mechanical and the psychological—and these three factors could not be divorced without the patient suffering. In the upper extremity much of what had been said about the lower limb applied, but in the science of artificial prosthesis it was axiomatic that the task of providing an artificial substitute for the lower limb was mere child's play in comparison with providing a substitute for the upper extremity. The hand and arm were more complicated mechanisms than the foot and leg. The requirements of foot and leg were locomotion and weight-bearing, those of the upper extremity were flexion, extension, abduction, adduction, pronation, supination, and, above all, ability to grip. Not a great deal could be done for the men who were unfortunate enough to suffer the loss of the upper extremity. Some of the substitutes were no good at all. The important thing, however, was that the operating surgeon should amputate with a view to the distinct type of prosthesis that had subsequently to be fitted to the stump. The co-operation existing at Roehampton between the operating surgeon, the limb-fitting surgeon, and the maker of artificial limbs was proving of benefit to all concerned. With regard to the length of stump, this should be sufficient to give adequate control over the prosthesis, and be free from adherent scars; the stump should be well covered, mobile, and free from pain. For this ideal stump several limbs were available. There could be no such thing as standardization or mass production in the manufacture of artificial limbs. It was not always the case that the longer the stump the greater the security and control. He was against the through-elbow amputation on account of surgical difficulties, scar tissue, malnutrition, and bony prominences, together with awkward, unsightly, ill-fitting prosthesis. If one had the chance it was well to amputate 2 inches above the epicondyle. Many surgeons regarded a very short forearm stump as practically useless, and said that, from the point of view of limb-fitting, nothing less than 3 inches of the ulna should be left; yet in many cases at Roehampton it had been possible to fit such stumps successfully with a special type of prosthesis. With regard to disarticulations at the wrist-joint, one of the chief reasons why this operation was performed was to preserve rotation at the wrist, but from the limb-fitting point of view it was not a desirable site. Captain Maxwell concluded with some remarks on the psychological effect on the patient of a well-fitting appliance, which changed the whole mental outlook to life. He spoke from special experience on this point as one who for twelve years had been giving instruction on the purely functional, not vocational, side to men who had lost their limbs, and he had seen, consequent upon

some adjustment of the limb, the whole attitude of a man change from despair to hope.

Sir HOLBURT WARING, in closing the discussion, said that the last speaker had mentioned three factors—the surgical, the technical, and the psychological—but surely there was a fourth, also interrelated—namely, the economic. It was very important to have manual training after the fitting of the limb.

At the end of the meeting several Roehampton patients who had been fitted with artificial lower extremities were introduced by Dr. Langdale-Kelham, and showed how excellently—almost normally—they could walk, climb stairs, and bend the limb.

THROAT INFECTIONS AND PUERPERAL FEVER.

AT a meeting of the North of England Obstetrical and Gynaecological Society, held at Sheffield on February 28th, with the president, Dr. J. W. BURNS, in the chair, a discussion took place on a paper on throat infections as an etiological factor in puerperal sepsis, read by Mr. W. W. King at Manchester on January 24th. Mr. King's paper, with certain additions, was published in the *Journal* of March 22nd, at page 533.

The PRESIDENT described two small epidemics which had occurred in a well-equipped hospital of fifteen beds. In both outbreaks some of the nurses had haemolytic streptococci in their throats, and others had non-haemolytic streptococci. Unfortunately he did not try, as Mr. King had done, to produce further evidence of association between the carriers and the cases which developed pyrexia. He had no doubt that the infection took place during the early days of the puerperium in both epidemics rather than during the actual labour. This was supported by the fact that since gloves and masks had been adopted in the wards no similar cases had occurred. Mr. King had focused attention on the haemolytic streptococci, but the president suggested that the non-haemolytic type was also capable of producing a virulent infection in the puerperal woman. Non-haemolytic streptococci could become very virulent by being passed through a second individual. They had therefore to guard their patients against all organisms which might be present in the throats of any of the attendants. Lying-in ward technique required reorganization and readjustment. At present very stringent rules were made for the labour ward, caps, masks, gowns, etc., were insisted upon, yet within twelve hours of the baby being born the mother had her vulval toilet carried out by a junior nurse who wore neither a mask nor gloves. The incidence of puerperal infection in the Rotunda Hospital was greatly reduced by insisting upon a separate bed-pan and douche-pan for each patient. These cases of spontaneous infection would be banished if more attention was paid to the nursing technique in the wards. All nurses ought to wear gloves and masks when carrying out their duties in connexion with the vulval toilet, and bed-pans ought to be boiled at once after use. He was particularly anxious that all nurses in the wards should wear gloves. Constant washing was liable to make the skin of the hand rough and cracked, and hence the nurse became a danger to herself and her patient. In conclusion, the president asked if the masks usually worn at operations afforded sufficient protection to the patient, and if Mr. King had had any experience in the treatment of cases of puerperal infection by streptococcal antitoxin.

Professor W. BLAIR BELL (Liverpool) said he agreed that streptococcal infection was often conveyed to patients from sore throats. Women appeared to have a greater liability to infection at labour than at other times. He referred to the correspondence between the zymotic and puerperal sepsis curves as a point in favour of Mr. King's thesis. The use of the term "autogenous" should be limited to direct infections from lesions already present in the patient herself before the onset of puerperal sepsis. Preparturitional vaginal infections by streptococci were not autogenous, but resulted from the introduction of organisms from without. He had called attention to the danger of late coitus in this respect at the Obstetrical Congress in 1925. The acidity of the amniotic fluid (*p*H about 5.5) made it a valuable antiseptic douche from above. The increased dangers of operations after the escape of the fluid might be explained in this way. Infection might be carried into lying-in wards by visitors. If it was impossible to exclude them their numbers should be strictly limited. Infection might be carried from one patient to another by bed-pans. He discussed the question of antisepsis *versus* asepsis, and pointed out the danger of the latter to those who have no aseptic conscience. He suggested that the Ministry of Health should supply a team to investigate outbreaks of puerperal infection in maternity wards. The control of the investigation would remain in the hands of the surgeon.

Professor MILES H. PHILLIPS (Sheffield) expressed the hope that Mr. King's paper would lead to further critical investigation of throat infections as a factor in puerperal fever. The danger of such infections in midwifery was pointed out, as Mr King had said, by Kanter and Pilot in *Surgery, Gynecology and Obstetrics* (January, 1924); and Dame Janet Campbell, in *The Protection of Motherhood* (1927), gave details of epidemics in maternity hospitals which were associated with the presence of carriers of the haemolytic streptococcus. Experience in general, and especially abdominal, surgery had led the great majority of surgeons to insist on the use of a face mask. There were many recorded investigations of outbreaks of sepsis in surgical clinics which had resulted in the discovery that one or more members of the theatre staff carried haemolytic streptococci in the nose or throat, and no other source of infection had been found. Investigations of epidemics in various maternity hospitals had led to the same conclusions. In discussing the use of face masks in midwifery practice, he had heard it stated that such a precaution would lead to carelessness in the use of other more essential precautions, such as the proper use of antiseptics. Such a statement was absurd, and could be countered by that of other critics who pretended to believe that the use of masks in the operating theatre had its only virtue in reminding the theatre staff of the necessity to attend to all the details of aseptic technique. Other critics of this theory of droplet infection by carriers expressed the belief that everybody's throat contained the haemolytic streptococcus. Many investigations had shown the fallacy of this. Professor Phillips gave the following two instances in his experience. In November last he saw a young primipara who had had a rigor with a temperature of 102.8° F., with a pulse rate of 140, seventy-two hours after an easy forceps delivery. Swabs were taken from a small perineal wound, the lochial discharge, and the throats of the two doctors present at the labour, the nurse, the husband, and a housemaid; none of the throats yielded a streptococcus, the vaginal swabs grew staphylococcus only, and the patient's blood was sterile. She made a quick recovery. The second, a primigravida with a funnel-shaped pelvis, was delivered by Caesarean section a few hours after the onset of labour. The membranes were intact, and no vaginal examination had been made for several days. A bacteriological test of the vaginal secretions yielded no growth of streptococci. The operation was carried out in the gynaecological operating theatre with all the usual precautions, in the presence of several nurses and students. It was perfectly straightforward. In less than forty-two hours the patient was dead from a fulminating streptococcal infection. No case of wound infection occurred in that theatre during several weeks preceding and succeeding the operation. The throats of all the individuals present were investigated, and only one—that of the first assistant—contained haemolytic streptococci. At that time masks of thin butter muslin were used; but masks made of a single thickness of butter muslin had been shown by bacteriological tests to be quite ineffective. A mask of four thicknesses of surgical gauze (each of which is itself fourfold) was probably effective.

Dr. LEITH MURRAY (Liverpool) considered that further control experiments were necessary before the "droplet infection" theory could be accepted as conclusive. He did not think that wearing of masks would lead to a reduction in the incidence of sepsis, and described briefly

two cases of puerperal morbidity which had occurred in a hospital. The first was subsequently proved to be a case of scarlet fever. The throats of six of the fifteen attendants in this hospital yielded haemolytic streptococci, and in his opinion this incidence was the result rather than the cause of the morbidity in the scarlatinal cause.

Professor DOUGLAS (Sheffield) said that though identification of strains of streptococci was still very difficult, this fact should not hamper the search for carriers of the organism responsible for puerperal infection. The effect of introducing haemolytic strains by carriers was all the more noteworthy in view of the fact that a certain proportion of pregnant women harboured haemolytic streptococci in the vagina or cervix without developing trouble. Although actual proof was lacking of identity of strain in the suspected carriers and the cases reported by Mr. King, yet his thesis afforded such strong evidence that carriers formed an important source of infection that it was worthy of serious attention, and would form an important basis for the further attack on the problem of puerperal infection.

Mr. W. GORGH (Leeds) thought all throats contained streptococci. He considered there was another factor besides the presence of haemolytic streptococci in the causation of puerperal sepsis.

Mr. A. GORGH (Leeds) said that the reason why the morbidity rate had not fallen was possibly due to a greater proportion of primigravidae than in the earlier returns of the Registrar-General.

Mr. J. ERIC STACEY (Sheffield), while considering that every possible channel by which infection could occur ought to be closed, was not convinced that the throat was the main source from which the organisms were introduced. He said that Mr. King was not maintaining throat droplet infection as the sole or even the commonest source of puerperal morbidity, but that this was a method by which the organisms could obtain entry to the vaginal tract and thus cause sepsis. All would accept this to be true, but it should not be allowed to cloud other issues—for example, why in certain cases puerperal sepsis should develop and under similar conditions fail to appear in others. The vast majority of women subjected to spraying from the throat of an attendant developed no sepsis. Epidemics of haemolytic streptococcus infection occurred in gynaecological cases from time to time where all woro masks in the theatre which should be adequate to prevent droplet infection. A large number of deaths and morbid cases arose in which haemolytic streptococci were not the causal organism at all, and a few in which the throat could not be the source of infection—for example, cases of *Bacillus aerogenes capsulatus* infection. He had recently investigated the question of "failed forceps," and in a series of 152 cases there were 21 deaths, with 12 cases from puerperal sepsis. From only 3 of these 12 cases had haemolytic streptococci been isolated as the causal organisms. In 3 cases gas-forming organisms were found, and in the remaining 6 the organisms were non-haemolytic streptococci. The figures, though small, were significant of the fact that haemolytic streptococci were not necessarily present, and that trauma, associated with an exogenous source of infection—such, for example, as faecal infection—must not be lost sight of. In a faecal source of infection he included all those organisms which entered from the intestinal tract and were carried downwards from teeth, tonsils, and elsewhere in the tract, and thus entered the uterus via the perineum. He also considered that the question of the presence of pre-existing haemolytic streptococcus in the vagina had not been sufficiently elucidated.

Professor A. M. CONNELL (Sheffield), speaking from a general surgical aspect, thought that the individual herself must have haemolytic streptococci in her throat before throat infection could act as the causal agent.

Dr. STIRLING (M.O.H., Chesterfield) considered that the isolation of contacts in nospital was an almost insuperable obstacle to the control of this method of infection. Co-operation was necessary between family doctor, hospital, and public authorities.

Mr. W. W. KING, in replying, said he was glad that he had been able to convince all but one or two that droplet infection from the air passages of apparently healthy attendants was a source of great danger to parturient women. He did not exclude other sources of infection, so that the important points raised in regard to antiseptics and bed-pans were irrelevant to the question. It was premature to attempt to grade the importance of his thesis in the causation of puerperal fever, but he had produced sufficient evidence to satisfy reasonable people that this avenue of infection must be closed. It did not seem much to ask that obstetricians should adopt the same care for their maternity cases as they did for their gynaecological operations. In regard to controls, Mr. King suggested that the best test of the value of the theory would be the results obtained by the use of masks during the next five years, especially in maternity hospitals. He was confident that if the scheme was conscientiously carried out puerperal fever in "booked" cases in maternity hospitals would be as rare as suppuration in laparotomy wounds. In anticipation of the objection that a large proportion of the population had haemolytic streptococci in their throats during the winter months, Dr. Kirk, at his request, had examined swabs from the throats of fifty out-patients taken at random during the month of February, and only one was found to be a carrier. These results confirmed those given in his paper. As Professor Douglas had said, final proof of the identity of the streptococci in the carrier and victim could only be obtained when accurate classification of haemolytic streptococci was possible. Almost any organism could be carried to the patient in this way, including anaerobic organisms, which were well known to be occasional inhabitants of the throat. Mr. King found it easier to believe that *B. aerogenes capsulatus* could get into the vagina from the throat of an attendant than that it should get in on the doctor's hands or instruments. The latter was unhesitatingly accepted without proof, the former should be put to the test. In regard to "autogenous" infection, he accepted Professor Blair Bell's definition as being much more accurate. The theory of preparturitional infection as a cause of puerperal fever was all right in itself, but, as he had said in his paper, there was surprisingly little positive evidence in its favour. Dr. Leith Murray had referred to the relationship of scarlet fever to puerperal sepsis. In the case he reported the throats of the staff might have been infected from the patient who developed scarlet fever, but it was equally possible that the patient was the victim of the attendant carriers. The relatively small number of cases of puerperal infection had been put forward as an objection to the droplet theory. The same objection was made to the contagion theory of Semmelweis. No more was known to-day than was known a century ago as to why only a few of those subjected to infection develop the disease. Infection from the rectum was improbable, as it so rarely followed gynaecological operations. In answer to the president and others, he thought that masks made of four layers of butter muslin were probably satisfactory if not worn for more than two or three hours. He agreed with Dr. Stirling that it was not always possible to exclude known carriers from the wards, and, if so, reliance had to be placed upon masks. Great watchfulness was necessary to see that the masks were always worn both for vaginal examinations and for the administration of enemata, as well as for delivery and the subsequent nursing.

MYOMECTOMY.

AT a meeting of the Edinburgh Obstetrical Society, held on March 12th, with the president, Dr. H. S. DAVIDSON, in the chair, Dr. LEITH MURRAY (Liverpool) read a paper on myomectomy, embodying a record of 154 consecutive cases.

Dr. Leith Murray expressed the view that this operation was not performed as frequently as it should be; conservation in gynaecology, although it could be overdone, was an excellent feature of our modern work. Women were marrying at a later age than formerly, and their uteri, therefore, were more likely to contain fibroids. He hoped to demonstrate statistically: (1) that myomectomy—in his own experience the largest number removed had been 41—could be removed from the substance of the

uterus as safely as the uterus itself could be removed; and (2) that the after-results as regards comfort, menstrual function, and safe fertility were satisfactory in all but a negligible fraction of cases. Married women in all but thirties or early forties should not be submitted to hysterectomy merely because they had been sterile for years: cases were quoted in confirmation of this statement. The speaker did not think it right to interfere in any radical way with the natural probabilities of married life, even in women with several children, provided that the fibroids necessitating intervention could be removed with moderate ease. To broaden his statement and survey he had included in his paper 60 cases in the non-pregnant woman already reported (*Journal of Obstetrics and Gynæcology of the British Empire*, 1926, vol. xxxiii, No. 2); later information was available in a good percentage of these. He emphasized the need for separating in any statistical survey cases of myomectomy in the non-pregnant from those operated on during pregnancy. The two operations were largely different in character and conduct; in the former alone was an attempt made to remove every fibroid. Of 137 cases of fibroids subjected to operation in the non-pregnant state tumours of appreciable size were in each instance "dug out" of the musculature of the uterus: all intraligamentary fibroids were excluded. He detailed the contraindications, and expressed his belief that neither any variety or degree of degeneration nor infection—a very rare complication—was a real barrier. The technique of the operation was outlined, with special stress on haemostasis. Mechanical or elastic clamps were considered unnecessary, and there appeared to be no need to reduce the resulting uterine mass by any trimming or excision of excess; involution occurred just as well and as quickly without this additional step. Examination at the end of three months showed that the uterus was normal in size and shape whatever its outline was at the end of operation. He recommended that the uterine cavity should be explored in all cases where haemorrhage was a symptom.

Dr. Leith Murray then discussed his series of 137 cases of myomectomy in the non-pregnant under the headings of: (1) statistical comparison with hysterectomy; (2) recurrence of fibroids and sub-equent operations for any reason; and (3) pregnancies following operation. During the three and a half years ending December, 1929, he had performed 1 myomectomy to 2.8 hysterectomies for fibroids; for the preceding two and a half years the relationship had been 1 to 3.7. Only one case had ended fatally, by embolism (0.73 per cent.), whereas his mortality for hysterectomy for fibroids was 1.5 per cent. Two cases of recurrence had been observed, and in one of these the uterine cavity, which four years later contained a fibroid polyp, had been explored at the original operation. Of the first series of 60 cases, 35 women under the age of 42 had had a reasonable chance of pregnancy, and of these 34.3 per cent. had had one or more pregnancies since operation. The later series of 77 cases had already produced, in 49 possible cases, 22.4 per cent. of pregnancies. For the total of 137 cases up to the end of 1929 the percentage of pregnancies was over 27. Detailed analyses were given of the ages of patients, the number and condition of the fibroids, the symptoms leading to operation, convalescence, and after-histories. The speaker called attention to the relatively small number of cases (15) operated on during pregnancy; he believed that many patients with acute necrobiotic degeneration could be tided over the danger period by repeated doses of morphine, and evidence of this was given in 10 cases operated on during pregnancy, 6 went to full term or viability, 3 miscarried within twenty-four hours—probably inevitably—and 1 died as the result of an injudicious operation on a diabetic patient. Five cases were associated with a diagnosis of intrauterine death, three strangely enough proving to be hydatid moles; all did well, and in two instances there had been a further pregnancy. Of two cases at full term with irreducible obstruction, one was easily delivered by Cæsarean section of a living child, and four fibroids, the largest the size of a red intramural fibroid) the size of a fist, were removed; the other patient died of a low-grade peritonitis, six days after a Cæsarean section with an extensive myomectomy, which operation did not appear to have contributed to the fatal result.

Dr. Leith Murray concluded that he had no reason to alter his opinion, expressed in 1925, that myomectomy was an operation of less difficulty and danger than was supposed, was available in a very large percentage of cases of women of child-bearing age, and should in such circumstances be preferred to hysterectomy.

The Edinburgh Pregnancy Diagnosis Station.

Dr. EDWIN ROBERTSON read a paper based on the work of the Pregnancy Diagnosis Station which has been established at the Department of Animal Genetics in Edinburgh University, where specimens of urine are examined by the Zondek-Aschheim test. his figures relating to a rather longer period than that covered by Dr. Crew's report, which was published in the *Journal* of April 5th (p. 652). Dr. Robertson said that microscopical examination of the ovaries showed that the action of the pregnancy urine was one of maturation. The comparatively massive dosage used in the test probably deranged the maturation processes involved, thus producing the atypical haemorrhages seen in the follicles. The ovary-stimulating factors in the pregnancy urine were similar to the ovary-stimulating factors which could be extracted from the placenta, not only in the type of reaction produced in the ovary—namely, maturation—but also in being destroyed, precipitated, and dissolved by the same agents. Therefore the active substances in the urine were probably only product of the placenta excreted for some reason, as yet undefined. Hence a positive test was a placental sign and indicated, at least, the presence of placental elements. The function of the ovary depended upon extraovarian factors, which were for the most part situated in the anterior lobe of the pituitary, and it had been shown that the ovary-stimulating powers of the placenta were similar to those of the anterior lobe of the pituitary. Wiesner had explained this mutual relationship in a most convincing way: "The internal secretion of the ovary is necessary for the inception and maintenance of the conditions of pregnancy, and the stimulus of the placental hormones is required for the continuation of the ovarian function beyond the initial phase which occurs under pituitary influence." This particular role of the pituitary and the activity of the placenta were reflected in the urine of pregnancy, therefore urine which would produce ovarian maturation came probably from a pregnant woman. The results of the station incorporated 997 tests, of which 479 had been controlled; 13 of these cases were labelled incorrect, but 4 were so designated through a misinterpretation of the test result by the clinician. Therefore, with only 9 incorrect results out of 479 tests, the degree of accuracy of the test was about 98.12 per cent. Apart from the diagnosis of pregnancy the test was useful in detecting the presence of active placental elements and also hydatidiform mole and chorion epithelioma Incomplete abortions, ectopic pregnancies, missed abortions and cases of retained placenta had all conformed to the "rule" that, if the elements present were alive and active, a positive result would be obtained, and vice versa. It was thought that both hydatidiform mole and chorion epithelioma were extremely active in the production of the ovary-stimulating substances, and that the presence of lutein cysts in association with these conditions was strong evidence in favour of this view.

SPLENECTOMY IN SPLENIC ANÆMIA.

A MEETING of the Section of Medicine of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on March 14th, with the president, Dr. R. J. ROWLETTE, in the chair Dr F. X. CALLAGHAN showed a case of splenic anæmia treated by splenectomy, the patient being a boy aged 12, who was admitted to hospital in January.
